LIQUID REFILL CONTAINER FOR REFILLING LIQUID DISCHARGE APPARATUS WITH LIQUID, AND REUSE SYSTEM USING LIQUID REFILL CONTAINER

Abstract

A liquid refill container for refilling a liquid discharge apparatus with liquid includes a liquid storage portion, a pouring portion, and a cap portion. The liquid storage portion is made of a metal and contains liquid. The pouring portion is removeably connected to the liquid storage portion and has an outlet for pouring the liquid. The cap portion is removeably attached to the pouring portion and covers the outlet.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] The present application is a continuation of U.S. patent application Ser. No. 18/332,624, filed on Jun. 9, 2023, which is a continuation of U.S. patent application Ser. No. 17/556,254, filed on Dec. 20, 2021, now issued as U.S. Pat. No. 11,708,179 on Jul. 25, 2023, which claims priority from Japanese Patent Application No. 2021-028711 filed Feb. 25, 2021, which are hereby incorporated by reference herein in their entireties.

BACKGROUND

Field

[0002] The present disclosure relates to a liquid refill container for refilling a liquid discharge apparatus with liquid, and a reuse system using a liquid refill container.

Description of the Related Art

[0003] As a liquid discharge apparatus typically an ink jet recording apparatus, there is known a liquid discharge apparatus in which a cartridge-shaped liquid storage tank is set in an apparatus main body and liquid is supplied from the liquid storage tank to a liquid discharge head of the liquid discharge apparatus.

[0004] On the other hand, a liquid discharge apparatus as described in Japanese Patent Laid-Open No. 2015-178280 has come to be used. In the liquid discharge apparatus, a liquid storage tank is fixed to the liquid discharge apparatus in advance, liquid is refilled from the outside to the liquid storage tank with the use of a bottle-shaped liquid refill container or the like, and the liquid storage tank is not replaced.

[0005] In the liquid discharge apparatus as described in Japanese Patent Laid-Open No. 2015-178280, liquid is refilled by opening the inlet of the liquid storage tank, removing a cap at the tip end of the liquid refill container, and inserting the tip end of the liquid refill container to the inlet. A liquid refill container entirely made of resin is generally used not only from the viewpoint that manufacturing through injection molding or the like is easy but also from the viewpoint of easiness of disposal after refilling of liquid is complete.

[0006] Resin liquid refill containers can be reused by separately collecting the liquid refill containers without simply disposing of the liquid refill containers and then, for example, melting the liquid refill containers. However, as a further direct reuse method, a method of filling a liquid refill container, which is empty as a result of pouring liquid, with liquid again without disposal is conceivable.

[0007] However, it is found that there is an inconvenience that, when liquid is repeatedly filled with the use of a liquid refill container entirely made of resin, the liquid refill container itself, particularly, a liquid storage portion directly containing liquid, degrades and, as a result, reuse becomes difficult.

SUMMARY

[0008] The present disclosure provides a liquid refill container suitable for reuse.

[0009] According to an aspect of the present disclosure, a liquid refill container for refilling a liquid

discharge apparatus with liquid includes a liquid storage portion made of a metal and configured to contain liquid, a pouring portion removeably connected to the liquid storage portion and having an outlet for pouring the liquid, and a cap portion removeably attached to the pouring portion and covering the outlet.
[0010] Further features of the present disclosure will become apparent from the following description of exemplary embodiments with reference to the attached drawings.

Description

BRIEF DESCRIPTION OF THE DRAWINGS
[0011] FIG. **1** is a perspective view showing the outer appearance of a liquid discharge apparatus.
[0012] FIG. **2** is a perspective view showing the internal configuration of the liquid discharge apparatus.
[0013] FIG. **3**A is an enlarged perspective views of a portion in which liquid storage tanks are stored.
[0014] FIG. **3**B is an enlarged plan views of the portion in which the liquid storage tanks are stored.
[0015] FIG. **4** is a side view showing the outer appearance of a liquid refill container.
[0016] FIG. **5**A is an exploded side view showing the parts of the liquid refill container.
[0017] FIG. **5**B is a cross-sectional view showing the parts of the liquid refill container.
[0018] FIG. **6** is a flowchart of a manufacturing method for a liquid refill container.
[0019] FIGS. **7**A to **7**C are perspective views each showing the structure of packing.
DESCRIPTION OF THE EMBODIMENTS
[0020] Hereinafter, an embodiment of the present disclosure will be described with reference to the attached drawings. Like reference signs are assigned to portions having the same functions in the drawings, and the description thereof may be omitted.
Liquid Discharge Apparatus
[0021] A liquid discharge apparatus that is refilled with liquid from a liquid refill container will be described. FIG. **1** is a perspective view showing the outer appearance of the liquid discharge apparatus according to an embodiment of the present disclosure. The liquid discharge apparatus **1** shown in FIG. **1** is a so-called ink jet recording apparatus. The liquid discharge apparatus **1** shown in FIG. **1** includes a casing **11**, and liquid storage tanks **12** disposed inside the casing **11**. Each of the liquid storage tanks **12** contains ink that is liquid to be discharged to a record medium (not shown).
[0022] FIG. **2** is a perspective view showing the internal configuration of a relevant part of the liquid discharge apparatus **1** shown in FIG. **1**. In FIG. **2**, the liquid discharge apparatus **1** includes a conveying roller **13** for conveying a record medium (not shown), a carriage **15** provided with a recording head **14** that discharges liquid, and a carriage motor **16** for driving the carriage **15**. In other words, the liquid discharge apparatus **1** of the present embodiment is a so-called serial ink jet recording apparatus. A record medium is a medium on which an image is formed by liquid discharged from the recording head **14**. Examples of the record medium include paper, cloth, optical disk label side, plastic sheet, and overhead projector (OHP) sheet.
[0023] The liquid container tanks **12** are fixedly mounted in the liquid discharge apparatus **1**. Each of the liquid storage tanks **12** is a tank that contains liquid. Liquid contained in each liquid storage tank **12** is supplied to the recording head **14** via a liquid channel **17** and is discharged from the recording head **14**. When the liquid discharge apparatus **1** is an ink jet recording apparatus, the liquid is so-called ink. Here, four-color (for example, cyan, magenta, yellow, and black) inks are used as liquid, and the four-color liquid storage tanks **12***a* to **12***d* that respectively contain color inks. In other words, black ink is contained in the liquid storage tank **12***a*, cyan ink is contained in the liquid storage tank **12***b*, magenta ink is contained in the liquid storage tank **12***c*, and yellow ink

is contained in the liquid storage tank **12***d*. The liquid storage tanks **12***a* to **12***d* each are disposed at the front side portion of the liquid discharge apparatus **1** inside the casing **11**.

[0024] FIG. **3**A is an example of an enlarged perspective view of a portion of the liquid discharge apparatus **1** shown in FIGS. **1** and **2** where the liquid storage tanks **12***b* to **12***d* are stored. FIG. **3**B is a plan view of the portion where the liquid storage tanks **12***b* to **12***d* shown in FIG. **3**A are stored when viewed from above. Each of the liquid storage tanks **12** includes a liquid storage tank body **121** for containing liquid, and a communication channel **122** that communicates with a liquid chamber in the liquid storage tank body **121**. In addition, the liquid storage tank **12** includes an attachable tank cover (not shown) to, during times other than during refilling of liquid, cover the communication channel **122** and hermetically seal the liquid chamber inside the liquid storage tank body **121**. To refill the liquid storage tank **12** with liquid, the tank cover is opened, the outlet **22***a* of a liquid refill container **2** (described later) is inserted in the communication channel **122**, and liquid is poured. When the liquid chamber is hermetically sealed with the tank cover during times other than during refilling of liquid, it is possible to reduce evaporation of liquid inside the liquid storage tank **12**. The communication channel **122** includes two channels extending in parallel with each other in a vertical direction inside, and liquid in the liquid refill container **2** is configured to be poured into the liquid storage tank **12** by gas-liquid exchange. A socket **18** is provided at a portion of the liquid discharge apparatus **1** where the outlet **22***a* of the liquid refill container **2** is inserted. The socket **18** has protruding portions **19** that protrude inward from an inner peripheral wall. The socket **18** is provided for each liquid storage tank **12** and the shape of the protruding portions **19** is varied among the sockets **18**. Only the liquid refill container **2** associated with the shape of the protruding portions **19** is able to be fitted to the socket **18**. Thus, it is possible to prevent a refill mistake of liquid (a mistake of color). The protruding portions **19** are provided symmetrically at 180° with respect to the central axis of the communication channel **122**. When recessed portions to be engaged with the protruding portions **19** of the socket **18** of the liquid discharge apparatus **1** are provided at the pouring portion **22** of the liquid refill container **2**, it is possible to position the liquid refill container **2** with the socket **18**, and it is possible to pour predetermined liquid to the liquid storage tank **12**.

Liquid Refill Container

[0025] FIG. **4** is a side view showing the outer appearance of the liquid refill container **2** to refill the liquid storage tank **12** with liquid.

[0026] The liquid refill container **2** includes a liquid storage portion **21** that contains liquid, a pouring portion **22** connected to the liquid storage portion **21**, and a cap portion **23** attached to the pouring portion **22**. The liquid refill container **2** has a bottle shape as a whole.

[0027] The liquid storage portion **21** contains liquid, occupies a half or more length of the liquid refill container **2** in the longitudinal direction, and serves as a main body portion of the liquid refill container **2**. Since the liquid storage portion **21** is a portion that contains liquid, the liquid storage portion **21** can occupy two thirds or more of the length of the liquid refill container **2** in the longitudinal direction when the capacity is taken into consideration.

[0028] As will be described later, the liquid storage portion **21** is made of a metal. The pouring portion **22** has an outlet **22***a* that is an outlet at the time of pouring liquid contained in the liquid storage portion **21**. The pouring portion **22** is a portion having the function of pouring liquid. The cap portion **23** is attached to the pouring portion **22** and covers the outlet **22***a*. The cap portion **23** has a role in isolating the inside of the liquid storage portion **21** from outside air.

[0029] FIGS. **5**A and **5**B show the parts of the liquid refill container **2** of FIG. **4**. FIG. **5**A is an exploded side view of the parts of the liquid refill container **2**. FIG. **5**B is a cross-sectional view of the liquid refill container **2** after the parts of the liquid refill container **2** shown in FIG. **5**A are assembled. The liquid storage portion **21** of the liquid refill container **2** is made up of a bottle threaded portion **21***a* formed at the upper part, and a bottle storage portion **21***b* formed at the lower part. The bottle threaded portion **21***a* and the bottle storage portion **21***b* are integrated and are made

of the same metal. The pouring portion **22** is made up of an outlet **22***a* for pouring liquid, a nozzle external threaded portion **22***b* on which an external thread structure is formed on the outer side, and a nozzle internal threaded portion **22***c* on which an internal thread structure is formed on the inner side. The pouring portion **22** is made of a resin. Examples of the material used to form the pouring portion **22** include polyethylene (PE) and polypropylene (PP).

[0030] The nozzle internal threaded portion **22***c* of the pouring portion **22** is screwed to the bottle threaded portion **21***a* of the liquid storage portion **21**. The pouring portion **22** is attached to the liquid storage portion **21** by means of screwing. Packing **28** is disposed at the connecting portion between the pouring portion **22** and the liquid storage portion **21**. The packing **28** seals the connecting portion. The packing **28** has flexibility. Examples of the material used to form the packing **28** include butyl rubber, fluororubber, hydrogenated nitrile rubber, ethylene propylene dien monomer (EPDM), and silicone rubber.

[0031] FIGS. **7**A to **7**C are perspective views each showing the packing **28**. The packing **28** having a structure shown in FIG. **7**A has two annular projections **28***a*, **28***b* on the liquid storage portion side. The structure of the packing **28** is the same as that of the packing **28** shown in FIG. **5**B. The area between the projections **28***a*, **28***b* is in contact with the liquid storage portion **21**. The side faces of projections **28***a*, **28***b* are also in contact with the liquid storage portion **21**. The projections **28***a*, **28***b* sandwich both sides of a contact surface to increase sealing property. The packing **28** shown in FIG. **7**B has no projection, and a portion on the liquid storage portion side is a flat smooth surface **28***c*. By not providing a projection on the liquid storage portion side of the packing **28**, it is beneficial that the packing **28** and the liquid storage portion **21** are easily positioned. The packing **28** shown in FIG. **7**C has an annular projection **28***d* on the liquid storage portion side. When the number of projections is one, it is possible to ensure positioning and sealing in a balanced manner. A projection of the packing **28** may be provided at a portion on the pouring portion side. A projection may be in contact with a member of the pouring portion and caused to be deformed.

[0032] The rubber hardness of the packing **28** is preferably a Shore D hardness of higher than or equal to 10 and more preferably a Shore D hardness of higher than or equal to 30. When the Shore D hardness is too low, sealing decreases. On the other hand, when the Shore D hardness is too high as well, the packing **28** is hard to deform, and sealing also decreases. In terms of this point, the Shore D hardness is preferably lower than or equal to 80, more preferably lower than or equal to 55, and further preferably lower than or equal to 45.

[0033] The structure around the cap portion **23** will be described. As shown in FIG. **5**B, a cap threaded portion **23***a* having an internal thread structure is disposed on the inner side of the lower part of the cap portion **23**. The cap threaded portion **23***a* is screwed to the nozzle external threaded portion **22***b* of the pouring portion **22**. A cap seal portion **23***b* is provided at the upper side of the cap portion **23**. The cap seal portion **23***b* and part of the outlet **22***a* are fitted to each other by means of screwing, and the outlet **22***a* is hermetically sealed. As described above, the nozzle internal threaded portion **22***c* is screwed to the bottle threaded portion **21***a*, and the pouring portion **22** and the liquid storage portion **21** are joined by means of screwing.

[0034] The liquid storage portion **21** of the liquid refill container **2** is made of a metal. The metal used to form the liquid storage portion **21** can be, for example, any one of a stainless steel, a steel, a porcelain enamel, and aluminum. After liquid is poured from the liquid refill container **2** to the liquid storage tank **12**, the liquid refill container **2** is collected, and the metal liquid storage portion **21** is washed. Thus, it is possible to reuse the liquid storage portion **21**. Examples of a washing method for the liquid storage portion **21** include a washing method using water or hot water and a washing method using a predetermined detergent. After washing, when liquid is poured into the liquid storage portion **21** again and the liquid storage portion **21** is set in the liquid refill container **2** for use, the liquid refill container **2** is reusable, so it is environmentally beneficial. Although a scheme to reuse the liquid refill container **2** will be described later, it is easy to wash the liquid refill container **2** because the liquid refill container **2** is made of a metal. When the liquid refill

container **2** is made of a resin, liquid adhering to the liquid refill container **2** may be difficult to be completely removed. When the liquid refill container **2** is made of a metal, the liquid refill container **2** is less prone to degradation even when washed and filled with liquid again, so it is more suitable to be reused as a liquid refill container. For the above reasons, in the embodiment of the present disclosure, the liquid refill container **2** is made of a metal usually not used for a liquid refill container for refilling a liquid discharge apparatus with liquid.

[0035] The internal capacity of the liquid storage portion **21** is not limited. On the assumption that liquid is poured into the liquid storage tank **12** and is discharged from a liquid discharge head of a liquid discharge apparatus, the internal capacity of the liquid storage portion **21** is preferably greater than or equal to 10 ml and less than or equal to 200 ml. Examples of the shape of a cross section perpendicular to the height direction (longitudinal direction) of the liquid storage portion **21** include circle, square, and rectangle. The liquid storage portion **21** can have a cylindrical shape or a rectangular parallelepiped shape.

[0036] A seal **24** is provided on the inner side of the pouring portion **22**. The seal **24** has an opening at its tip end. The communication channel **122** is to be inserted in the opening. When the cap portion **23** is opened and the communication channel **122** is not inserted, a valve **25** is urged by a spring **26** toward the opening to seal the opening. Examples of the material used to form the seal **24** include a rubber and an elastomer. Examples of the material used to form the valve **25** include polyethylene (PE) and polypropylene (PP). Examples of the material used to form the spring **26** include a stainless steel. An end portion of the spring **26** on the side opposite to the valve **25** side is fixed by a holder **27**. Examples of the material used to form the holder **27** include polyethylene (PE) and polypropylene (PP). The holder **27** is fixed to the pouring portion **22** by welding.

[0037] At the time of refilling (supplying) the liquid storage tank **12** with liquid from the liquid refill container **2**, initially, the cap portion **23** is removed. Then, the liquid refill container **2** is fitted to the liquid storage tank **12**. Thus, the liquid discharge apparatus-side communication channel **122** (FIG. **3**A) is inserted into the pouring portion **22** through the opening of the seal **24** of the liquid refill container **2**. The valve **25** is opened as a result of the insertion. Liquid in the liquid refill container **2** is supplied to the liquid chamber of the liquid storage tank body **121** via the communication channel **122** due to the water head difference.

[0038] As shown in FIG. **5**B, by providing the cap portion **23** with a protrusion, the valve **25** is opened by the protrusion at the time when the cap portion **23** is removed. Thus, when the air pressure in the liquid refill container **2** is higher than the outside air pressure as well, flooding of liquid from the liquid storage tank **12** as a result of rapid inflow of liquid into the liquid storage tank **12** is reduced at the time of supplying the liquid storage tank **12** with liquid.

[0039] As described above, when the nozzle internal threaded portion **22***c* is screwed to the bottle threaded portion **21***a*, the pouring portion **22** is attached to the liquid storage portion **21**. Here, a user removes the cap portion **23** from the pouring portion **22** by rotating the cap portion **23** and pours liquid. However, if a user erroneously rotates (rotates in a direction opposite to the rotation direction of screwing) between the pouring portion **22** and the liquid storage portion **21** and separates the pouring portion **22** and the liquid storage portion **21** from each other, liquid may adhere to the hand. To reduce the possibility, the cap portion **23** and the liquid storage portion **21** can be in different color systems, and the pouring portion **22** and the liquid storage portion **21** can be in the same color system. Since the liquid storage portion **21** is made of a metal, when the liquid storage portion **21** is not colored, the liquid storage portion **21** mostly has a gray color with the L* value of L*a*b* color specification system in the CIE color specification system in a range of greater than or equal to 10 and less than or equal to 95. For this reason, in this case, the pouring portion **22** can also have a gray color with the L* value of L*a*b* color specification system in the CIE color specification system in a range of greater than or equal to 10 and less than or equal to 95. On the other hand, the cap portion **23** has a color of which the L* value does not fall within the range greater than or equal to 10 and less than or equal to 95, that is, for example, a white color.

[0040] As another method that prevents a user from rotating the pouring portion **22** and the liquid storage portion **21** relative to each other to separate the pouring portion **22** and the liquid storage portion **21** from each other, there is a method of setting rotation directions. This is a method to set the rotation directions at the time of screwing the pouring portion **22** and the liquid storage portion **21** to each other to reverse directions (opposite directions) to the rotation directions at the time of screwing the cap portion **23** and the pouring portion **22** to each other. In this case, of course, the rotation directions for separation are respectively reverse directions, so a user is difficult to erroneously rotate the pouring portion **22** and the liquid storage portion **21** in a separating direction. More specifically, when the cap portion **23** is rotated in the clockwise direction with respect to the pouring portion **22** to screw the cap portion **23** and the pouring portion **22**, the rotation direction can be, on the contrary, set such that the pouring portion **22** is rotated in the counterclockwise direction with respect to the liquid storage portion **21** to screw the pouring portion **22** and the liquid storage portion **21** to each other.

Reuse System

[0041] An example of a reuse system for a liquid refill container will be described below. A user who newly purchases a liquid discharge apparatus or a user who already owns a liquid discharge apparatus makes a contract on a use of a liquid refill container with a maker that manufactures liquid refill containers. In accordance with the contract, a liquid refill container is delivered from the maker to the user. The user pours liquid in the liquid refill container into the liquid storage tank to refill liquid into the liquid storage tank. An empty liquid refill container is returned from the user to the maker. The maker removes the liquid storage portion from the returned liquid refill container and washes the liquid storage portion, and manufactures a liquid refill container by reusing the liquid storage portion and assembling the pouring portion and the cap portion to the liquid storage portion. On the other hand, the user orders a liquid refill container to the maker at the stage at which a predetermined amount of liquid in the liquid storage tank of the liquid discharge apparatus has been used. In accordance with a request from the user, the maker delivers a liquid refill container to the user again. The user supplies the liquid storage tank with liquid in the delivered liquid refill container and returns the empty liquid refill container to the maker again. When the liquid storage portion is circulated between the maker and the user in this way, the liquid refill container can be reused. In this way, a liquid refill container delivered from the maker can be the one washed and reused from a liquid refill container returned in the past from the user who has ordered the liquid refill container. However, a liquid refill container returned from another user may also be washed, reused, and delivered. An order for a liquid refill container may be automatically placed in accordance with the amount of usage of liquid in a liquid discharge apparatus or a usage period of the apparatus itself.

[0042] The above-described example is a scheme that assumes to wash and reuse only the liquid storage portion **21**. The pouring portion **22** and the cap portion **23** are difficult to be washed when made of a resin, and an assembly inside the pouring portion **22** is also difficult to be washed by removing the assembly, so, when only the liquid storage portion **21** is reused, reliability as a liquid refill container improves. However, parts other than the liquid storage portion **21** may be washed and reused. The packing **28** in the liquid refill container **2** is difficult to be reused due to concerns about creep; however, parts other than the packing **28** are relatively easily reused. A washing method for parts may be a washing method similar to that of the liquid storage portion **21** (described later).

[0043] The flow of a manufacturing method for the liquid refill container **2** will be described with reference to FIG. **6**. The packing **28** and the seal **24** are press-fitted and inserted to the pouring portion **22** by using a handpress or the like. The valve **25** and the spring **26** are inserted into the holder **27**. The assembled pouring portion **22** and holder **27** are welded to each other by using ultrasonic welding or the like to make a unit part of the pouring portion **22**.

[0044] On the other hand, outer appearance inspection, washing, and drying processes are

performed on the liquid storage portion **21**. The reused liquid storage portion **21** may have adhering liquid inside. For this reason, the inside of the liquid storage portion **21** is washed. The description will be made with reference to a specific example. Initially, the liquid storage portion **21** is immersed in pure water for 30 minutes to clean adhering liquid. Subsequently, the liquid storage portion **21** is washed for 60 minutes by using 60° C. pure water (hot water), and dried for 120 minutes in a tank at 60° C.

[0045] Processes after that will be described with reference to a specific example. After liquid is poured into the dried liquid storage portion **21**, the unit part of the pouring portion **22** is assembled. A torque during the assemblage is assumed as 4.0 N.Math.m. Subsequently, the cap portion **23** is assembled to the pouring portion **22**. A torque during the assemblage is assumed as 2.0 N.Math.m. The finished liquid refill container **2** undergoes a decompressed upside down test under an environment of 0.6 MPa for 60 minutes, and liquid leakage from the packing **28** and the cap portion **23** is inspected. After the inspection is passed, the liquid refill container **2** is packed and shipped to a user.

[0046] In this way, a liquid refill container is able to be reused.

[0047] While the present disclosure has been described with reference to exemplary embodiments, it is to be understood that the disclosure is not limited to the disclosed exemplary embodiments. The scope of the following claims is to be accorded the broadest interpretation so as to encompass all such modifications and equivalent structures and functions.

Claims

1. A liquid refill container for refilling a liquid discharge apparatus with liquid, the liquid refill container comprising: a liquid storage portion made of a metal and configured to contain the liquid; a pouring portion removeably connected to the liquid storage portion and having an outlet for pouring the liquid; and a cap portion removeably attached to the pouring portion and covering the outlet, wherein a liquid stop valve is provided inside the pouring portion, wherein the liquid stop valve includes an orifice portion, a valve element, and a spring configured to bias the valve element to close a gap between the orifice portion and the valve element, and wherein the cap portion has a protrusion, and the protrusion is configured to provide the gap between the orifice portion and the valve element at a time when the cap portion is attached.

2. The liquid refill container according to claim 1, wherein the metal is any one of the following: a stainless steel, a steel, a porcelain enamel, or aluminum.

3. The liquid refill container according to claim 1, wherein the pouring portion is made of a resin.

4. The liquid refill container according to claim 1, wherein the cap portion is in a color system that is different from a color system in which the pouring portion is in.

5. The liquid refill container according to claim 4, wherein the cap portion has a color with an L* value that does not fall within a range greater than or equal to 10 and less than or equal to 95.

6. The liquid refill container according to claim 1, wherein the liquid storage portion occupies two thirds or more of a length of the liquid refill container in a longitudinal direction.

7. The liquid refill container according to claim 1, wherein the pouring portion has a recessed portion which engage with a protruding portion that is disposed in a socket of the liquid discharge apparatus where an inserted outlet is inserted.

8. The liquid refill container according to claim 1, wherein the liquid refill container is configured to contain ink as the liquid.

9. The liquid refill container according to claim 1, wherein the liquid refill container is a bottle configured to contain ink as the liquid.

10. The liquid refill container according to claim 1, wherein the liquid discharge apparatus comprises a liquid storage tank and the liquid is to be supplied by the pouring portion being fitted to the liquid storage tank.

11. A liquid refill container for refilling a liquid discharge apparatus with liquid, the liquid refill container comprising: a liquid storage portion made of a metal and configured to contain the liquid; a pouring portion removeably connected to the liquid storage portion and having an outlet for pouring the liquid; and a cap portion removeably attached to the pouring portion and covering the outlet, wherein the pouring portion and the cap portion are connected by screwing, wherein the pouring portion and the liquid storage portion are connected by screwing, and wherein a rotation direction in which the cap portion is rotated to be screwed to the pouring portion and a rotation direction in which the pouring portion is rotated to be screwed to the liquid storage portion are opposite to each other.

12. The liquid refill container according to claim 11, wherein the metal is any one of the following: a stainless steel, a steel, a porcelain enamel, or aluminum.

13. The liquid refill container according to claim 11, wherein the pouring portion is made of a resin.

14. The liquid refill container according to claim 11, wherein the cap portion is in a color system that is different from a color system in which the pouring portion is in.

15. The liquid refill container according to claim 14, wherein the cap portion has a color with an L* value that does not fall within a range greater than or equal to 10 and less than or equal to 95.

16. The liquid refill container according to claim 11, wherein the liquid storage portion occupies two thirds or more of a length of the liquid refill container in a longitudinal direction.

17. The liquid refill container according to claim 11, wherein the pouring portion has a recessed portion which engage with a protruding portion that is disposed in a socket of the liquid discharge apparatus where an inserted outlet is inserted.

18. The liquid refill container according to claim 11, wherein the liquid refill container is configured to contain ink as the liquid.

19. The liquid refill container according to claim 11, wherein the liquid discharge apparatus comprises a liquid storage tank and the liquid is to be supplied by the pouring portion being fitted to the liquid storage tank.

20. A remanufacturing method of a liquid refill container for refilling a liquid discharge apparatus with liquid, the liquid refill container including: a liquid storage portion made of a metal and configured to contain the liquid; a pouring portion removeably connected to the liquid storage portion and having an outlet for pouring the liquid; and a cap portion removeably attached to the pouring portion and covering the outlet, wherein a liquid stop valve is provided inside the pouring portion, wherein the liquid stop valve includes an orifice portion, a valve element, and a spring configured to bias the valve element to close a gap between the orifice portion and the valve element, and, the method comprising; removing the liquid storage portion from the pouring portion, washing the liquid storage portion, pouring the liquid into the liquid storage portion, and assembling the pouring portion and the cap portion to the liquid storage portion.
