United States Patent	12384467
Kind Code	B2
Date of Patent	August 12, 2025
Inventor(s)	Nishimura; Yoshikazu et al.

Vehicle-body front structure including a reinforcement structure and a floor reinforcement

Abstract

A vehicle-body front structure includes a partition wall portion which demarcates a space inside a vehicle cabin, a motor arrangement portion which is formed by causing a part of the partition wall portion to bulge to an inside of the vehicle cabin and in which at least a part of a traveling motor is capable of being arranged, a reinforcement member which is inclined to be positioned lower toward vehicle rear, and a floor reinforcement which extends in a vehicle front-rear direction. A closed cross-section is configured with the motor arrangement portion, the reinforcement member, and the floor reinforcement.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS (1) The present application is a continuation of U.S. application Ser. No. 18/108,017, filed on Feb. 10, 2023, which claims priority to U.S. Provisional Application No. 63/444,377, filed on Feb. 9, 2023, which claims benefit of Japanese Patent Application 2022-026759, filed Feb. 24, 2022, Japanese Patent Application 2022-026760, filed Feb. 24, 2022, Japanese Patent Application 2022-026762, filed Feb. 24, 2022, Japanese Patent Application 2022-026764, filed Feb. 24, 2022, and Japanese Patent Application 2022-026766, filed Feb. 24, 2022, the entire contents of each of which are incorporated herein by reference.

BACKGROUND

Field

(1) The present disclosure relates to a vehicle-body front structure for an electric vehicle, for example.

Description of the Related Art

(2) For example, Patent Literature 1 discloses an electric vehicle in which batteries are installed below a floor panel. In a front portion of the floor panel of the vehicle in Patent Literature 1, a center member is provided which extends in a vehicle front-rear direction. In the center member, plural protruding portions which are protruded upward and extend in the vehicle front-rear direction and recess portions which are recessed downward among the protruding portions are formed.

CITATION LIST

Patent Literature

(3) [Patent Literature 1] Japanese Patent Laid-Open No. 2021-62676

SUMMARY

(4) Incidentally, because in a vehicle including an engine in related art, an engine and accessory components configuring an intake-and-exhaust system, and so forth are provided in an engine room, in a case where an impact load is exerted from front in a collision, the vehicle absorbs the impact load by deforming components in the engine room, front side frames, and so forth.

(5) However, because in a case of an electric vehicle as in Patent Literature 1, accessory components are largely decreased compared to an engine, there is a concern that an impact load cannot sufficiently be absorbed.

(6) The present disclosure has been made in consideration of such problems, and an object thereof is, in an electric vehicle, to inhibit retreat of a traveling motor into an inside of a vehicle cabin in a collision while disposing the traveling motor as close to a vehicle rear side as possible and thereby sufficiently securing a crash stroke in the collision in the front-rear direction.

Means for Solving the Problems

(7) To achieve the above object, a first aspect of the present disclosure can be based on a vehicle-body front structure for an electric vehicle in which a traveling motor is installed in a vehicle front portion. The vehicle-body front structure includes: a partition wall portion which is provided to extend in a vehicle width direction in the vehicle front portion and demarcates a vehicle cabin inside space; a motor arrangement portion which is formed by causing a part of the partition wall portion to bulge to an inside of a vehicle cabin and in which at least a part of the traveling motor installed on an outside of the vehicle cabin inside space is capable of being arranged; a reinforcement member which extends from an upper portion of the motor arrangement portion to vehicle rear and is inclined to be positioned lower toward the vehicle rear; and a floor reinforcement which extends in a vehicle front-rear direction below the reinforcement member and along a floor panel. A first closed cross-section is configured with the motor arrangement portion, the reinforcement member, and the floor reinforcement.

(8) In this configuration, because the motor arrangement portion formed in the partition wall portion bulges to the inside of the vehicle cabin, it becomes possible to cause the traveling motor to be close to the vehicle rear side. Accordingly, a crash stroke in a collision is sufficiently secured in a front-rear direction.

(9) Further, in a collision in which an impact load from front is exerted, an obstacle possibly enters a space in front of the partition wall portion, and the obstacle exerts a load in a retreating direction on the traveling motor. The traveling motor on which the load in the retreating direction is exerted pushes rearward the motor arrangement portion. In this case, because the motor arrangement portion forms the first closed cross-section together with the reinforcement member which is inclined downward toward a rear side and the floor reinforcement and rigidity of the vicinity of the motor arrangement portion is enhanced, rearward deformation of the motor arrangement portion is inhibited. In addition, the motor arrangement portion is supported, from rear, by the reinforcement member and the floor reinforcement. Consequently, retreat of the traveling motor to the inside of the vehicle cabin is inhibited.

(10) In a second aspect of the present disclosure, a connecting member, which couples a front portion of the reinforcement member and a front portion of the floor reinforcement together in an up-down direction, can be provided in the vehicle rear of the motor arrangement portion.

(11) In this configuration, because the front portions of the reinforcement member and of the floor reinforcement can be coupled with each other, rigidity of the vicinity of the motor arrangement portion can further be enhanced.

(12) In a third aspect of the present disclosure, a second closed cross-section can be configured with the connecting member and the motor arrangement portion.

(13) In this configuration, because the second closed cross-section, which is configured with the reinforcement member and the floor reinforcement and is other than the first closed cross-section, is formed on a rear side of the motor arrangement portion, rigidity of the vicinity of the motor arrangement portion can further be enhanced.

- (14) In a fourth aspect of the present disclosure, the vehicle-body front structure may include a cross member which is fixed to the floor panel on a vehicle rear side of the motor arrangement portion and extends in the vehicle width direction. A rear portion of the floor reinforcement can be connected with an intermediate portion of the cross member in the vehicle width direction.
- (15) In this configuration, because the floor reinforcement is coupled with the cross member with high rigidity, an effect of inhibiting rearward deformation of the motor arrangement portion is further enhanced.
- (16) In a fifth aspect of the present disclosure, a front portion of the floor reinforcement can be connected with a lower portion of the motor arrangement portion.
- (17) In this configuration, because the front portion of the floor reinforcement and the front portion of the reinforcement member are respectively connected with portions, which are spaced apart in the up-down direction, of the motor arrangement portion, rigidity of the motor arrangement portion can be enhanced in a wide range.

Advantages

- (18) As described above, at least a part of a traveling motor is arranged in a motor arrangement portion which is formed by causing a part of a partition wall portion to bulge to an inside of a vehicle cabin, and a closed cross-section is configured with the motor arrangement portion, a reinforcement member, and a floor reinforcement. Accordingly, retreat of the traveling motor to the inside of the vehicle cabin in a collision can be inhibited while the traveling motor is disposed as close to a vehicle rear side as possible and a crash stroke in the collision is thereby sufficiently secured in a front-rear direction.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

- (1) The scope of the present disclosure is best understood from the following detailed description of exemplary embodiments when read in conjunction with the accompanying drawings.
- (2) FIG. 1 is a side view of an electric vehicle according to an embodiment, in which a part of the electric vehicle is omitted.
- (3) FIG. 2 is a side view illustrating a state where the electric vehicle is divided into a lower structure and an upper structure.
- (4) FIG. 3 is a plan view of the lower structure.
- (5) FIG. 4 is a plan view which illustrates a front-side portion of the lower structure while enlarging that.
- (6) FIG. 5 is a bottom view which illustrates the front-side portion of the lower structure while enlarging that and from which a power train, shock absorbers, springs, and hubs, and so forth are omitted.
- (7) FIG. 6 is a cross-sectional perspective view illustrating a vehicle-body front portion.
- (8) FIG. 7 is a cross-sectional view illustrating the vehicle-body front portion.
- (9) FIG. 8 is a cross-sectional view illustrating a front-side power train and its vicinity of the vehicle-body front portion while enlarging those.
- (10) FIG. 9 is a cross-sectional view illustrating the vehicle-body front portion which is sectioned in a horizontal direction at an intermediate portion in an up-down direction.
- (11) FIG. 10 is a cross-sectional view taken along line X-X in FIG. 9.
- (12) FIG. 11 is a diagram which corresponds to FIG. 9 and which illustrates a state where a reinforcement member is detached.
- (13) FIG. 12 is a cross-sectional view illustrating a structure example where the reinforcement member is mounted on a lid body of a battery unit.
- (14) FIG. 13 is a perspective view illustrating an inside of a vehicle cabin in a state where the

reinforcement member is detached.

(15) FIG. 14 is a bottom view of the vehicle-body front portion from which the power train, a battery unit, suspension apparatuses, and so forth are omitted.

(16) FIG. 15 is a cross-sectional view which illustrates the upper structure from which batteries and so forth are omitted and which corresponds to line XV-XV in FIG. 9.

DETAILED DESCRIPTION

(17) Non-limiting embodiments of the present disclosure will hereinafter be described in detail based on drawings. Note that the description of preferable embodiments in the following is substantially only about examples and is not at all intended to restrict the present disclosure, applications thereof, or uses thereof.

(18) FIG. 1 is a left side view of an electric vehicle (electric automobile) 1 including a vehicle-body front structure A according to a non-limiting embodiment of the present disclosure. As illustrated in FIG. 2, the electric vehicle 1 includes a lower structure 2 and an upper structure 3. In FIG. 1, a front bumper, a rear bumper, front and rear wheels, and so forth are omitted and are illustrated by imaginary lines, and each portion is schematically illustrated. In FIG. 2, in addition to the components omitted in FIG. 1, doors, a bonnet hood, a front fender, window glass, front and rear lighting devices, interior materials, and so forth are omitted, and each portion is schematically illustrated.

(19) Note that in the description of the embodiment, a vehicle front side will simply be referred to as “front”, a vehicle rear side will simply be referred to as “rear”, a vehicle right side will simply be referred to as “right”, and a vehicle left side will simply be referred to as “left”. A right-left direction of the vehicle is a vehicle width direction.

(20) As illustrated in FIG. 1, the electric vehicle 1 is a passenger automobile. The electric vehicle 1 may be any of a sedan type, a hatch-back type, a minivan type, and so forth, and its shape is not particularly limited. As illustrated in FIG. 2, in the electric vehicle 1, a vehicle cabin R1 is formed which serves as a staying space (vehicle cabin inside space) for an occupant. As illustrated in FIG. 1, a front seat (seat) S1 is provided on a front side in the vehicle cabin R1, and a rear seat S2 is provided in rear of the front seat S1 in the vehicle cabin R1. In the rear of the rear seat S2, a trunk R2 is provided in accordance with necessity. The vehicle cabin R1 and the trunk R2 are provided to the upper structure 3. Note that in the vehicle cabin R1, only the front seat S1 may be provided, or a third row seat may be provided in the rear of the rear seat S2.

(21) Meanwhile, a space (front-side space) in front of the vehicle cabin R1 as a front portion of the electric vehicle 1 can be set as a power chamber R3, for example. That is, as illustrated in FIG. 3, the vehicle-body front structure A is provided to the electric vehicle 1 which includes a front-side traveling motor M1 installed in a vehicle front portion, a rear-side traveling motor M2 installed in a vehicle rear portion, batteries B supplying electric power to the traveling motors M1 and M2, and a battery casing 10 housing the batteries B. The battery casing 10 is disposed below a floor panel 70 described later. FIG. 4 is a plan view of a front-side power train PT1 and its vicinity, and FIG. 5 is a bottom view in a case where the front-side power train PT1 is omitted.

(22) The front-side traveling motor M1 produces a driving force for driving left and right front wheels FT, and the front-side power train PT1 is configured with only the front-side traveling motor M1 or with the front-side traveling motor M1, a speed reducer, a transmission, and so forth. Further, the rear-side traveling motor M2 illustrated in FIG. 2 and FIG. 3 produces a driving force for driving left and right rear wheels RT (illustrated in FIG. 1), and a rear-side power train PT2 is configured with only the rear-side traveling motor M2 or with the rear-side traveling motor M2, a speed reducer, a transmission, and so forth.

(23) In the present embodiment, the rear-side traveling motor M2 is configured to produce a highest output (maximum torque) which is high compared to the front-side traveling motor M1, and the rear-side traveling motor M2 has a larger size than the front-side traveling motor M1. Accompanying that, the rear-side power train PT2 becomes larger than the front-side power train

PT1. Note that the rear-side traveling motor M2 may produce the highest output which is low compared to the front-side traveling motor M1, or the rear-side traveling motor M2 and the front-side traveling motor M1 may produce equivalent highest outputs. Further, only the front-side power train PT1 may be provided, or only the rear-side power train PT2 may be provided. Further, for example, in a case of a large-sized vehicle, the front-side traveling motor M1 and the rear-side traveling motor M2 are installed which are large compared to a small-sized vehicle.

(24) As illustrated in FIG. 2, the lower structure 2 includes the battery casing 10, a pair of left and right front side frames 11 and 12 which extend forward in front of the battery casing 10, and a pair of left and right rear frame 13 and 14 which extend rearward in the rear of the battery casing 10. A reference numeral 11 denotes the left front side frame, and a reference numeral 12 denotes the right front side frame. A reference numeral 13 denotes the left rear frame, and a reference numeral 14 denotes the right rear frame. In FIG. 2, a lid body 35 (described later) of the battery casing 10 is detached.

(25) In a case of a common electric automobile, a battery casing is often formed as a separate body from a vehicle body and is often detachable from a portion below a floor; however, in the present embodiment, not only the battery casing 10 but also the left and right front side frames 11 and 12 and the left and right rear frames 13 and 14 are integrated with the battery casing 10, and the front side frames 11 and 12 and the rear frames 13 and 14 together with the battery casing 10 are detachable from the upper structure 3.

(26) Specifically, the electric vehicle 1 of the present embodiment is configured to be capable of being divided, in an up-down direction, into the lower structure 2 having the battery casing 10 and the upper structure 3 forming the vehicle cabin R1 and the trunk R2. Being capable of being divided in the up-down direction means that without using welding, adhesion, or the like, the lower structure 2 is integrated with the upper structure 3 by using fastening members such as bolts, nuts, and screws. Accordingly, because the lower structure 2 can be separated from the upper structure 3 in accordance with necessity when maintenance or repairs are performed after the electric vehicle 1 is passed into the hands of a user, high maintainability is achieved. Note that fastening members used in the following description include bolts, nuts, screws, and so forth.

(27) Here, as a vehicle-body structure of an automobile, a vehicle-body structure of a ladder frame type has been known. In a case of the vehicle-body structure of the ladder frame type, the vehicle-body structure is being capable of being divided, in the up-down direction, into a ladder frame and a cabin, but the ladder frame continuously extends in a front-rear direction and thus mainly receives a collision load in a front collision and a rear collision. In a side collision, the ladder frame only subsidiarily receives a collision load, and the collision load is mainly received by the cabin. As described above, in the vehicle-body structure of the ladder frame type, usually, different members receive collision loads between the front collision and rear collision and the side collision.

(28) On the other hand, in a case of the electric vehicle 1 of the present embodiment, the lower structure 2 having the front side frames 11 and 12 and the rear frame 13 and 14 and the upper structure 3 are capable of being divided; however, a technical idea of the present embodiment is largely different from the vehicle-body structure of the ladder frame type in related art in the point that in both cases of the front collision and rear collision and the side collision, a collision load is received by the lower structure 2 and the upper structure 3, and the collision load is capable of being dispersedly absorbed by both of the structures 2 and 3. In the following, structures of the lower structure 2 and the upper structure 3 will be described in detail.

(29) (Lower Structure)

(30) First, the lower structure 2 will be described. The lower structure 2 includes the front and rear power trains PT1 and PT2, the front wheels FT, the rear wheels RT, front suspension apparatuses 20, rear suspension apparatuses 21, and so forth in addition to the battery casing 10, the front side frames 11 and 12, and the rear frames 13 and 14. Forms of the front suspension apparatus 20 and the rear suspension apparatus 21 are not particularly specified.

(31) A battery unit BY is configured with the battery casing **10** and the batteries B housed in an internal portion of the battery casing **10**, but in addition to those, for example, a battery cooling device and so forth may be included in the battery unit BY.

(32) The battery casing **10** is a large casing which is formed, below the floor panel **70** of the upper structure **3**, to be spanned from a left end portion vicinity to a right end portion vicinity of the floor panel **70** and to be spanned from a front end portion vicinity to a rear end portion vicinity of the floor panel **70**. As described above, the battery casing **10** is disposed in a wide range of a lower region of the floor panel **70**, and it thereby becomes possible to install the battery B with a large capacity in the electric vehicle **1**. The battery B may be a lithium-ion battery, a solid-state battery, or the like or may be another secondary cell. Further, the battery B may be a so-called battery cell or may be a battery pack housing plural battery cells. In the present embodiment, the battery B is configured with a battery pack, and plural battery packs are installed in a state where those are aligned in the front-rear direction and the left-right direction.

(33) The battery casing **10** includes a left-side battery frame **30**, a right-side battery frame **31**, a front-side battery frame **32**, a rear-side battery frame **33**, a bottom plate **34**, and the lid body **35** (illustrated in FIG. **4**) which covers the batteries B from above. Note that FIG. **3** illustrates a state where the lid body **35** is detached.

(34) The left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** are configured with an extruded material or the like of an aluminum alloy, for example, but may be configured with an aluminum alloy plate material or a press-formed material of a steel plate as well. The bottom plate **34** can be configured with an extruded material. In the following description, “extruded material” denotes an extruded material of an aluminum alloy, and “press-formed material” denotes an aluminum alloy plate material or a press-formed material of a steel plate. Further, each member may be configured with a casting, for example.

(35) All of cross-sectional shapes of the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** in respective orthogonal directions to their longitudinal directions are rectangular shapes. Further, the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** are all arranged at the same height and extend in generally horizontal directions.

(36) The left-side battery frame **30** and the right-side battery frame **31** are outer-side battery frames which extend in the front-rear direction on vehicle-width-direction outer sides of the batteries B. The left-side battery frame **30** is provided to a left-side portion of the battery casing **10** and extends in the front-rear direction along a left side sill **74**. The left-side battery frame **30** is fixed to the left side sill **74** by fastening members or the like. The right-side battery frame **31** is provided to a right-side portion of the battery casing **10** and extends in the front-rear direction along a right side sill **75**. The right-side battery frame **31** is fixed to the right side sill **75** by fastening members or the like.

(37) Further, the front-side battery frame **32** is provided to a front portion of the battery casing **10** and extends in the left-right direction. In a front view, at least a part of the front-side traveling motor M1 configuring the front-side power train PT1 is positioned so as to overlap with at least a part of the front-side battery frame **32**, that is, an intermediate portion of the front-side battery frame **32** in the vehicle width direction. Further, the rear-side battery frame **33** is provided to a rear portion of the battery casing **10** and extends in the left-right direction.

(38) A left end portion of the front-side battery frame **32** is connected with a front end portion of the left-side battery frame **30**, and a right end portion of the front-side battery frame **32** is connected with a front end portion of the right-side battery frame **31**. A left end portion of the rear-side battery frame **33** is connected with a rear end portion of the left-side battery frame **30**, and a right end portion of the rear-side battery frame **33** is connected with a rear end portion of the right-side battery frame **31**. Consequently, the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** are members which configure a

rack frame formed to surround all of the batteries B in a plan view.

(39) The bottom plate **34** extends generally horizontally and is fixed to lower surfaces of the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33**. Further, the lid body **35** is fixed to upper surfaces of the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33**. In other words, the lid body **35** is mounted on the battery frames **30** to **33**. When the lid body **35** is mounted on the battery frames **30** to **33**, for example, fastening members may be used, or adhesion, welding, or the like may be used. Consequently, a battery housing space S housing the batteries B (illustrated in FIG. 2) is marked off and formed with the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, the rear-side battery frame **33**, the bottom plate **34**, and the lid body **35**.

(40) The size of the battery housing space S can be changed in accordance with the capacity of the installed batteries B. The size of the battery housing space S is capable of being easily changed by changing lengths of the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** and a shape of the bottom plate **34**. For example, in a case where the electric vehicle **1** is a small vehicle which has a short wheelbase and narrow treads, the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, the rear-side battery frame **33** are made short, the shapes of the bottom plate **34** and the lid body **35** are made small in response to the shortening, and the battery housing space S thereby becomes small in accordance with the small vehicle. On the other hand, in a case of a large vehicle, the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** are made long, the shapes of the bottom plate **34** and the lid body **35** are made large in response to the elongation, and the battery housing space S thereby becomes large in accordance with the large vehicle. In a case where the left-side battery frame **30**, the right-side battery frame **31**, the front-side battery frame **32**, and the rear-side battery frame **33** are configured with the extruded material, the lengths can easily be changed. Further, the bottom plate **34** can be configured with the extruded material, and its shape can thereby easily be changed.

(41) An upper portion of the battery housing space S may be closed by the above lid body **35** or may be closed by the floor panel **70** of the upper structure **3**. In the battery housing space S, other than the batteries B, a cooling device cooling the batteries B, a heating device heating the batteries B, and so forth (temperature adjustment devices) can also be provided. Further, electric power of the batteries B is supplied to the traveling motors M1 and M2 via a control device. In addition, it is possible to charge the batteries B via a charging socket, a contactless charger, or the like.

(42) As illustrated in FIG. 2, in the internal portion of the battery casing **10** configuring the battery unit BY, as strength members extending in the left-right direction, first to third inside-casing members (inside-unit members) **25A**, **25B**, and **25C** are provided. All of heights of the first to third inside-casing members **25A**, **25B**, and **25C** are the same and are generally the same as the heights of the left-side battery frame **30** and so forth. The inside-casing members **25A**, **25B**, and **25C** may be configured with extruded material or may be configured with press-formed material. In the present embodiment, three inside-casing members **25A**, **25B**, and **25C** are provided, but the number of inside-casing members **25A**, **25B**, and **25C** may be increased or decreased in accordance with the dimension of the battery casing **10** in the front-rear direction. The first to third inside-casing members **25A**, **25B**, and **25C** are second members.

(43) The first to third inside-casing members **25A**, **25B**, and **25C** are arranged at distances from each other in the front-rear direction, the first inside-casing member **25A** is in a foremost position, and the third inside-casing member **25C** is in a rearmost position. A lower portion of each of the inside-casing members **25A**, **25B**, and **25C** is fixed to an upper surface of the bottom plate **34**. Further, a left end portion of each of the inside-casing members **25A**, **25B**, and **25C** is fixed to an inner surface (right-side surface) of the left-side battery frame **30**, and a right end portion of each of the inside-casing members **25A**, **25B**, and **25C** is fixed to an inner surface (left-side surface) of the

right-side battery frame **31**. In other words, the inside-casing members **25A**, **25B**, and **25C** are members which connect the left-side battery frame **30** and the right-side battery frame **31** together. (44) In the internal portion of the battery casing **10**, as strength members extending in the front-rear direction, a front central member (inside-unit member) **26** and first to third rear central members (inside-unit members) **27** to **29** are provided. The front central member **26** and the first to third rear central members **27** to **29** are arranged at generally the same heights and are provided at a center of the battery casing **10** in the left-right direction. Lower end portions of the front central member **26** and the first to third rear central members **27** to **29** are mounted on the upper surface of the bottom plate **34**. The front central member **26** and the first to third rear central members **27** to **29** are first members. The front central member **26** and first to third rear central members **27** to **29** and the first to third inside-casing members **25A**, **25B**, and **25C** intersect with each other.

(45) The front central member **26** is arranged between the front-side battery frame **32** and the first inside-casing member **25A**, a front end portion of the front central member **26** is fixed to a central portion of the front-side battery frame **32** in the left-right direction, and a rear end portion of the front central member **26** is fixed to a central portion of the first inside-casing member **25A** in the left-right direction. Consequently, the front-side battery frame **32** is a member which extends so as to connect the front end portions of the left-side battery frame **30** and the right-side battery frame **31** with the front end portion of the front central member **26**.

(46) The first rear central member **27** is arranged between the first inside-casing member **25A** and the second inside-casing member **25B**, a front end portion of the first rear central member **27** is fixed to the central portion of the first inside-casing member **25A** in the left-right direction, and a rear end portion of the first rear central member **27** is fixed to a central portion of the second inside-casing member **25B** in the left-right direction. Further, the second rear central member **28** is arranged between the second inside-casing member **25B** and the third inside-casing member **25C**, a front end portion of the second rear central member **28** is fixed to the central portion of the second inside-casing member **25B** in the left-right direction, and a rear end portion of the second rear central member **28** is fixed to a central portion of the third inside-casing member **25C** in the left-right direction. Further, the third rear central member **29** is arranged between the third inside-casing member **25C** and the rear-side battery frame **33**, a front end portion of the third rear central member **29** is fixed to the central portion of the third inside-casing member **25C** in the left-right direction, and a rear end portion of the third rear central member **29** is fixed to a central portion of the rear-side battery frame **33** in the left-right direction. Consequently, because the first to third inside-casing members **25A**, **25B**, and **25C** and the front central member **26** and first to third rear central members **27** to **29** are disposed in a lattice manner in the internal portion of the battery casing **10** and are coupled with each other, a reinforcement effect for the battery casing **10** is further enhanced.

(47) When an imaginary straight line extending in the front-rear direction is presumed in a plan view, the positions of the front central member **26** and the first to third rear central members **27** to **29** in the left-right direction are set such that the positions are arranged on the imaginary straight line. In other words, the first to third rear central members **27** to **29** are provided to be positioned on a rearward imaginary extension line of the front central member **26**. Note that the front central member **26** and the first to third rear central members **27** to **29** may be configured with one member which is continuous in the front-rear direction.

(48) As illustrated in FIGS. **4** to **6** and so forth, the vehicle-body front structure **A** includes the pair of left and right front side frames **11** and **12**, a frame bracket **40**, a first cross member **15**, a pair of left and right impact absorption members **16** and **17**, and a second cross member **19**. In the present embodiment, in addition to the above members, the vehicle-body front structure **A** includes a front member **18**, reinforcement members **19A** and **19B**, and so forth. Members configuring the vehicle-body front structure **A** are not limited to the above-described members and may include other members, apparatuses, devices, and so forth. Further, among the above-described members,

members which do not serve as configuration elements required for the present disclosure may be omitted.

(49) The front side frames **11** and **12** linearly and generally horizontally extend below left and right front main frames **72** and **73** provided to the upper structure **3**. The front side frames **11** and **12** can be configured with the extruded material, the press-formed material, or the like, for example. In the present embodiment, because the front side frames **11** and **12** are configured with the extruded material, their cross-sectional shapes in a direction orthogonal to the front-rear direction are generally equivalent from front end portions to rear end portions.

(50) The left and right front side frames **11** and **12** are mounted on the front-side battery frame **32** configuring the front portion of the battery casing **10** via the frame bracket **40**. In other words, rear portions of the left and right front side frames **11** and **12** are coupled with the front-side battery frame **32** by the frame bracket **40**. The frame bracket **40** is an integrally formed component of metal and extends in the left-right direction along a front surface of the front-side battery frame **32**. The rear portions of the left and right front side frames **11** and **12** are fixed to the frame bracket **40**. Metal which configures the frame bracket **40** is not particularly limited. For example, aluminum and so forth can be raised, and in this case, the frame bracket **40** can be formed by aluminum die-casting.

(51) The left and right front side frames **11** and **12** are mounted on the front-side battery frame **32** via the frame bracket **40**, but the rear portions of the front side frames **11** and **12** are caused to adjoin the front surface of the front-side battery frame **32**. Consequently, the front side frames **11** and **12** extend forward from the front-side battery frame **32**. Note that the rear portion of the front side frames **11** and **12** may slightly be spaced apart forward from the front surface of the front-side battery frame **32**. In this case also, viewing those as the whole, it can be considered that the front side frames **11** and **12** extend forward from the front-side battery frame **32**.

(52) The rear portion of the left front side frame **11** is arranged to correspond to a section on a left side of a center of the front-side battery frame **32** in the left-right direction. Further, the rear portion of the right front side frame **12** is arranged to correspond to a section on a right side of the center of the front-side battery frame **32** in the left-right direction.

(53) Accordingly, a distance between the left and right front side frames **11** and **12** becomes a predetermined distance. A distance between the rear portions of the front side frames **11** and **12** is set narrower than a distance between the left-side battery frame **30** and the right-side battery frame **31** of the battery casing **10**.

(54) Heights of the left and right front side frames **11** and **12** are generally the same. Further, the left and right front side frames **11** and **12**, the front central member **26** of the battery casing **10**, the left-side battery frame **30**, and the right-side battery frame **31** are disposed at generally the same heights.

(55) The left and right front side frames **11** and **12** extend to be positioned on the vehicle-width-direction outer sides toward the front. That is, the left front side frame **11** is inclined with respect to the imaginary straight line extending in the front-rear direction of the vehicle in a plan view so as to be positioned on a left side toward the front. Further, the right front side frame **12** is inclined with respect to the imaginary straight line extending in the front-rear direction of the vehicle in a plan view so as to be positioned on a right side toward the front. Accordingly, the distance between the left and right front side frames **11** and **12** (a separation distance in the vehicle width direction) becomes wider toward the front, and in a portion between the left and right front side frames **11** and **12**, a space C is formed in which all or a part of various components, apparatuses, devices, and so forth are capable of being arranged. Then, the space C has a shape which is enlarged in the vehicle width direction toward the front.

(56) An inclination angle of the left front side frame **11** with respect to the above imaginary straight line is equivalent to an inclination angle of a right front side frame **12** with respect to the above imaginary straight line. A front portion of the left front side frame **11** is arranged on a vehicle-

width-direction inner side of the left-side battery frame **30** of the battery casing **10**. Further, a front portion of the right front side frame **12** is arranged on the vehicle-width-direction inner side of the right-side battery frame **31** of the battery casing **10**.

(57) Further, as illustrated in FIG. **1**, positions, in the front-rear direction, of the front portions of the left and right front side frames **11** and **12** and of front portions of the left and right front main frames **72** and **73** of the upper structure **3** are set to generally the same positions.

(58) As illustrated in FIG. **5**, the frame bracket **40** includes a vertical plate portion **40a** which extends in the vehicle width direction and the up-down direction along the front surface of the front-side battery frame **32** and a lower plate portion **40b** which extends rearward from a lower edge portion of the vertical plate portion **40a** along the lower surface of the front-side battery frame **32** and which extends also in the vehicle width direction. The vertical plate portion **40a** and the lower plate portion **40b** are fixed to the front-side battery frame **32** by fastening members or the like. In such a manner, the vertical plate portion **40a** and the lower plate portion **40b** of the frame bracket **40** are respectively fixed to the front surface and the lower surface of the front-side battery frame **32**, and mounting rigidity of the frame bracket **40** on the front-side battery frame **32** can thereby be enhanced.

(59) In the vertical plate portion **40a** of the frame bracket **40**, a left-side insertion hole into which the rear portion of the left front side frame **11** is inserted and a right-side insertion hole into which the rear portion of the right front side frame **12** is inserted are formed at a distance in the vehicle width direction. The rear portion of the left front side frame **11** is fixed to the frame bracket **40** by an adhesive, a fastening member, or the like, for example, in a state where the rear portion is inserted into the left-side insertion hole.

(60) As illustrated in FIG. **4**, the frame bracket **40** includes a left-side upper plate portion **40e** which extends in the front-rear direction so as to cover an upper surface of the left front side frame **11** and a right-side upper plate portion **40f** which extends in the front-rear direction so as to cover an upper surface of the right front side frame **12**. The left-side upper plate portion **40e** and the upper surface of the left front side frame **11** are caused to adhere to each other by an adhesive, for example, and the right-side upper plate portion **40f** and the upper surface of the right front side frame **12** are similarly caused to adhere to each other. Accordingly, the left and right front side frames **11** and **12** can firmly be fixed to the frame bracket **40**.

(61) The frame bracket **40** has a left-side support portion **41** and a right-side support portion **42**, and the left-side support portion **41** and the right-side support portion **42** are integrally shaped with the vertical plate portion **40a** and the lower plate portion **40b**. The left-side support portion **41** is a portion which is arranged on the vehicle-width-direction outer side (left side) of the left front side frame **11** and supports the above front side frame **11** from the vehicle-width-direction outer side. Specifically, the left-side support portion **41** is protruded forward from a left-side portion of the left-side insertion hole in the vertical plate portion **40a** and extends along a left side surface of the left front side frame **11**. A front portion of the left-side support portion **41** reaches the vicinity of a central portion of the left front side frame **11** in the front-rear direction, and it thus becomes possible to support a wide range of the left-side support portion **41** by the left-side support portion **41**. It is also possible to cause the left front side frame **11** to adhere to the left-side support portion **41**.

(62) Further, the right-side support portion **42** is a portion which is arranged on the vehicle-width-direction outer side (right side) of the right front side frame **12** and supports the above front side frame **12** from the vehicle-width-direction outer side. Specifically, the right-side support portion **42** is protruded forward from a right-side portion of the right-side insertion hole in the vertical plate portion **40a** and extends along a right side surface of the right front side frame **12**. A front portion of the right-side support portion **42** reaches the vicinity of a central portion of the right front side frame **12** in the front-rear direction, and it thus becomes possible to support a wide range of the right-side support portion **42** by the right-side support portion **42**. It is also possible to cause the

right front side frame **12** to adhere to the right-side support portion **42**.

(63) On the vehicle-width-direction outer side of the frame bracket **40**, left and right suspension arms **20A** configuring the front suspension apparatuses **20** are supported to be swingable in the up-down direction. That is, in a portion on a left side of the left-side support portion **41** in the frame bracket **40**, a left-side arm mounting portion **43** is provided to be protruded to a left side. On the left-side arm mounting portion **43**, a base end portion of the left suspension arm **20A** is mounted to be rotatable around a shaft extending in the front-rear direction. Further, in a portion on a right side of the right-side support portion **42** in the frame bracket **40**, a right-side arm mounting portion **44** is provided to be protruded to a right side. On the right-side arm mounting portion **44**, a base end portion of the right suspension arm **20A** is mounted to be rotatable around a shaft extending in the front-rear direction.

(64) The first cross member **15** is a member, which is suspended between a portion of the left front side frame **11** which is spaced apart forward from the front-side battery frame **32** and a portion of the right front side frame **12** which is spaced apart forward from the front-side battery frame **32**, and linearly extends in the vehicle width direction. The first cross member **15** can also be configured with the extruded material, the press-formed member, or the like. In the present embodiment, a left-side portion of the first cross member **15** is fixed to the front portion of the left front side frame **11**, and a right-side portion of the first cross member **15** is fixed to the front portion of the right front side frame **12**. Consequently, the front portions of the left and right front side frames **11** and **12** are coupled with each other by the first cross member **15**.

(65) Further, the first cross member **15** is generally parallel with the front-side battery frame **32**. Accordingly, in a plan view, a rectangular shape (a trapezoidal shape in the present example) is formed with the first cross member **15**, the left and right front side frames **11** and **12**, and the front-side battery frame **32**, and a closed cross-section is configured when a horizontal cross section is seen.

(66) A left side of the first cross member **15** is protruded to the vehicle-width-direction outer side of the front portion of the left front side frame **11**. Further, a right side of the first cross member **15** is protruded to the vehicle-width-direction outer side of the front portion of the right front side frame **12**.

(67) The second cross member **19** is a member, which is arranged between the first cross member **15** and the front-side battery frame **32** and is suspended between the left front side frame **11** and the right front side frame **12**, and linearly extends in the vehicle width direction. The second cross member **19** can also be configured with the extruded material, the press-formed member, or the like. A dimension of the second cross member **19** in the vehicle width direction is shorter than a dimension of the first cross member **15** in the vehicle width direction.

(68) As also illustrated in FIG. 5, a left end portion of the second cross member **19** is fixed to a right side surface of the left front side frame **11** by adhesion, welding, a fastening member, or the like. A right end portion of the second cross member **19** is similarly fixed to a left side surface of the right front side frame **12**. Accordingly, intermediate portions of the left and right front side frames **11** and **12** in the front-rear direction are coupled with each other.

(69) Further, the second cross member **19** is generally parallel with the front-side battery frame **32**. Accordingly, in a plan view, a rectangular shape (a trapezoidal shape in the present example) is formed with the second cross member **19**, the left and right front side frames **11** and **12**, and the front-side battery frame **32**, and a closed cross-section is configured when a horizontal cross section is seen. Further, in a plan view, a rectangular shape is also formed with the second cross member **19**, the left and right front side frames **11** and **12**, and the first cross member **15**.

(70) As illustrated in FIG. 5, the left reinforcement member **19A** extends rearward from a portion on a left side of a central portion of the second cross member **19** in the vehicle width direction to the front-side battery frame **32**. A rear portion of the left reinforcement member **19A** is fixed to the right side surface of the left front side frame **11**. Further, the right reinforcement member **19B**

extends rearward from a portion on a right side of the central portion of the second cross member **19** in the vehicle width direction to the front-side battery frame **32**. A rear portion of the right reinforcement member **19B** is fixed to the left side surface of the right front side frame **12**.

(71) The left impact absorption member **16** is provided in front of the left front side frame **11** and is configured with a tubular member which extends forward. Further, the right impact absorption member **17** is provided in front of the right front side frame **12** and is configured with a tubular member which extends forward. Similarly to crush cans **72a** and **73a** of the upper structure **3**, the impact absorption members **16** and **17** perform compressive deformation due to an impact load from the front in a phase previous to deformation of the front side frames **11** and **12** and thereby absorb the impact load. As illustrated in FIG. **1**, positions, in the front-rear direction, of rear portions of the left and right impact absorption members **16** and **17** and of rear portions of the crush cans **72a** and **73a** of the upper structure **3** are set to generally the same positions.

(72) The rear portion of the left impact absorption member **16** is fixed to the front portion of the left front side frame **11**. A direction in which the left impact absorption member **16** extends is along the longitudinal direction of the left front side frame **11**, and an axis line of the impact absorption member **16** is positioned on a forward extension line of the front side frame **11**. Further, the rear portion of the right impact absorption member **17** is fixed to the front portion of the right front side frame **12**. A direction in which the right impact absorption member **17** extends is along the longitudinal direction of the right front side frame **12**, and an axis line of the impact absorption member **17** is positioned on a forward extension line of the front side frame **12**.

(73) As illustrated in FIG. **3**, FIG. **4** and so forth, the front member **18** is a member which is suspended between the left and right impact absorption members **16** and **17**. A portion on a left side of a central portion of the front member **18** in the vehicle width direction is fixed to a front portion of the left impact absorption member **16**, and a portion on a right side of the central portion of the front member **18** in the vehicle width direction is fixed to a front portion of the right impact absorption member **17**. Accordingly, the left and right impact absorption members **16** and **17** are coupled together by the front member **18**. As illustrated in FIG. **1**, positions, in the front-rear direction, of the front member **18** and of a front bumper reinforcement **87** of the upper structure **3** are set to generally the same positions, and the front member **18** is positioned directly below the front bumper reinforcement **87**.

(74) (Upper Structure)

(75) Next, the upper structure **3** will be described. As illustrated in FIG. **2**, the upper structure **3** includes the floor panel **70**, a dash panel (partition wall portion) **71**, the pair of left and right front main frames **72** and **73**, and the pair of left and right side sills **74** and **75**. A reference numeral **72** denotes the left front main frame, and a reference numeral **73** denotes the right front main frame. A reference numeral **74** denotes the left side sill, and a reference numeral **75** denotes the right side sill.

(76) The floor panel **70** configures a floor surface of the vehicle cabin **R1** and is formed with a steel plate or the like which extends in the front-rear direction and extends also in the left-right direction. A space above the floor panel **70** serves as the vehicle cabin **R1**. A roof **80** is provided to an upper portion of the vehicle cabin **R1**. Further, in both of left and right side portions of the upper structure **3**, front openings **3a** and rear openings **3b** are formed. As illustrated in FIG. **1**, the front opening **3a** and the rear opening **3b** are capable of being opened and closed by a front door **81** and a rear door **82**, respectively. A front door and a rear door are disposed on a right side of the upper structure **3** to be capable of being opened and closed.

(77) The left and right side sills **74** and **75** are respectively disposed in both of left and right end portions of the floor panel **70** to extend in the front-rear direction. The left end portion of the floor panel **70** is connected with an intermediate portion of the left side sill **74** in the up-down direction, and the right end portion of the floor panel **70** is connected with an intermediate portion of the right side sill **75** in the up-down direction. Upper-side portions of the side sills **74** and **75** are protruded

upward from connection portions with the floor panel **70**, and lower-side portions of the side sills **74** and **75** are protruded downward from the connection portions with the floor panel **70**. Because the battery casing **10** is arranged below the floor panel **70**, the battery casing **10** is arranged between the left and right side sills **74** and **75**, and in a vehicle side view, the lower-side portions of the side sills **74** and **75** overlap with the battery casing **10**. The battery casing **10** is fixed to the side sills **74** and **75**.

(78) The left and right front main frames **72** and **73** are disposed in a vehicle-body front portion and are highly strong members which extend in the front-rear direction. That is, the left and right front main frames **72** and **73** are positioned in front of the floor panel **70**, are positioned above the floor panel **70**, and are specifically disposed to extend forward from both of left and right sides in a lower portion of the dash panel **71**.

(79) The left and right front main frames **72** and **73** form a left-right symmetrical structure and can be configured by joining plural press-formed materials or can be configured with the extruded material, for example. A cross section of each of the front main frames **72** and **73** in a direction orthogonal to the front-rear direction is set larger than a cross section of each of the front side frames **11** and **12** of the lower structure **2** in the same direction. Accordingly, the front main frames **72** and **73** become thick and highly strong members compared to the front side frames **11** and **12**.

(80) Front end portions of the left and right front main frames **72** and **73** respectively have the crush cans **72a** and **73a** which perform compressive deformation in a front collision and absorb collision energy. The crush cans **72a** and **73a** are tubular members which extend in the front-rear direction. The crush cans **72a** and **73a** perform compressive deformation due to an impact load from the front in a phase previous to deformation of the front main frames **72** and **73** and thereby absorb the impact load. The front bumper reinforcement **87** extending in the left-right direction is fixed to front end portions of the left and right crush cans **72a** and **73a**.

(81) As illustrated in FIG. **6** to FIG. **9**, the dash panel **71** is a member for making off the vehicle cabin **R1** from the power chamber **R3**, and the dash panel **71** demarcates the vehicle cabin **R1**. The dash panel **71** is configured with a steel plate or the like, for example, extends in the left-right direction in the vehicle-body front portion, and extends also in the up-down direction. As illustrated in FIG. **9**, a pair of left and right suspension tower portions **90** and **91** are provided on both of left and right sides of a front portion of the upper structure **3**. A reference numeral **90** denotes the left suspension tower portion, and a reference numeral **91** denotes the right suspension tower portion.

(82) Each of the left and right suspension tower portions **90** and **91** is formed to bulge inward in the vehicle width direction. That is, the left suspension tower portion **90** is formed to bulge rightward from left-side portions of the power chamber **R3** and the vehicle cabin **R1** in a range from the power chamber **R3** to the vehicle cabin **R1**, its bulging range is set also in the up-down direction, and the left suspension tower portion **90** is capable of housing a part of the left front suspension apparatus **20** which will be described later and is provided to the lower structure **2**. An upper portion (for example, a shock absorber upper portion) of the left front suspension apparatus **20** is supported by an upper portion of the left suspension tower portion **90**. Further, the right suspension tower portion **91** is formed to bulge leftward from right-side portions of the power chamber **R3** and the vehicle cabin **R1** in a range from the power chamber **R3** to the vehicle cabin **R1**, its bulging range is set also in the up-down direction, and the right suspension tower portion **91** is capable of housing a part of the right front suspension apparatus **20** which will be described later and is provided to the lower structure **2**. An upper portion of the right front suspension apparatus **20** is supported by an upper portion of the right suspension tower portion **91**.

(83) As illustrated in FIG. **9**, on both of left and right sides of the front portion of the upper structure **3**, left and right front wheel wells **85** and **86** for housing the left and right front wheels **FT** are formed to bulge inward in the vehicle width direction. A reference numeral **85** denotes the left front wheel well, and a reference numeral **86** denotes the right front wheel well. The left front wheel well **85** is continuous with a rear side of the left suspension tower portion **90**, bulges

rightward from the left-side portion of the vehicle cabin **R1**, and is capable of housing the left front wheel FT. Further, the right front wheel well **86** is continuous with a rear side of the right suspension tower portion **91**, bulges rightward from the right-side portion of the vehicle cabin **R1**, and is capable of housing the right front wheel FT.

(84) As illustrated in FIG. **6** and FIG. **7**, a cowl portion **88** is provided above the dash panel **71**. The cowl portion **88** extends in the left-right direction from the upper portion of the left suspension tower portion **90** to the upper portion of the right suspension tower portion **91**. Further, a lower-side portion of the cowl portion **88** extends forward and reaches intermediate portions of the left and right suspension tower portions **90** and **91** in the front-rear direction.

(85) The dash panel **71** includes an upper-side panel portion (first partition wall portion) **71A** configuring an upper-side portion of the dash panel **71** and a lower-side panel portion (second partition wall portion) **71B** configuring a lower-side portion of the dash panel **71**. The upper-side panel portion **71A** and the lower-side panel portion **71B** may be configured respectively with separate members or may be configured with different portions of one member. In a case where the upper-side panel portion **71A** and the lower-side panel portion **71B** are configured with separate members, those may each be shaped into desired shapes and thereafter be integrated together by joining those, or two members may be joined together and thereafter be shaped into desired shapes.

(86) An upper end portion of the upper-side panel portion **71A** is connected with the lower-side portion of the cowl portion **88**. The upper-side panel portion **71A** extends in the left-right direction and also in the up-down direction and specifically extends from the intermediate portion of the left suspension tower portion **90** in the front-rear direction to the intermediate portion of the right suspension tower portion **91** in the front-rear direction.

(87) The upper end portion of the lower-side panel portion **71B** is connected with a lower end portion of the upper-side panel portion **71A**. Thus, the upper end portion of the lower-side panel portion **71B** extends in the left-right direction from the intermediate portion of the left suspension tower portion **90** in the front-rear direction to the intermediate portion of the right suspension tower portion **91** in the front-rear direction. Meanwhile, a lower-side portion which is lower than the upper end portion of the lower-side panel portion **71B** (hereinafter, referred to as a lower-side portion of the lower-side panel portion **71B**) is formed to be positioned further to the rear toward a lower position. The lower-side portion of the lower-side panel portion **71B** may be inclined or may be curved.

(88) A lower end portion (rear end portion) of the lower-side panel portion **71B** is connected with the front end portion of the floor panel **70**. Both of left and right sides of the lower-side portion of the lower-side panel portion **71B** are respectively connected with the left and right front wheel wells **85** and **86**, extend rearward to reach the left and right side sills **74** and **75**, and are respectively connected with the left and right side sills **74** and **75**.

(89) As illustrated in FIG. **6** to FIG. **9**, the front-side traveling motor **M1** is installed below the lower-side portion of the lower-side panel portion **71B**. In other words, the lower-side portion of the lower-side panel portion **71B** is arranged to cover the front-side traveling motor **M1** from above. As a configuration for making it possible to arrange the front-side traveling motor **M1** below the lower-side portion of the lower-side panel portion **71B**, the upper structure **3** includes the motor arrangement portion **71a**. The motor arrangement portion **71a** is a portion, in which at least a part of the front-side traveling motor **M1** is capable of being arranged, and is a bulging portion, which is formed by causing the lower-side portion of the lower-side panel portion **71B** to bulge to the inside of the vehicle cabin **R1**. FIG. **14** illustrates a state where the motor arrangement portion **71a** is seen from below.

(90) Specifically, the front-side traveling motor **M1** is arranged to span from a portion between the left and right suspension tower portions **90** and **91** to a portion between the left and right front wheel wells **85** and **86** and is thus positioned directly below the lower-side portion of the lower-side panel portion **71B**. The intermediate portion of the lower-side portion of the lower-side panel

portion **71B** in the vehicle width direction is caused to bulge upward such that at least an upper-side portion and a rear-side portion of the front-side traveling motor **M1** are housed, and this bulging portion configures the motor arrangement portion **71a**. Because a dimension of the motor arrangement portion **71a** in the left-right direction is set shorter than a dimension between the left and right front wheel wells **85** and **86**, both of left and right side areas of the motor arrangement portion **71a** are configured with inclined surfaces which are inclined downward toward the rear. In other words, because the motor arrangement portion **71a** is provided and it thereby becomes possible to cause the front-side traveling motor **M1**, that is, the front-side power train **PT1** to be close to the vehicle rear side, a crash stroke in a head-on collision or the like is sufficiently secured in the front-rear direction.

(91) In the motor arrangement portion **71a**, the speed reducer and the transmission, which configure the front-side power train **PT1**, a casing which houses those, and so forth may be arranged. Further, in the motor arrangement portion **71a**, a control device which controls the front-side traveling motor **M1** and a wire harness may be arranged. When a surface of the motor arrangement portion **71a**, which faces a lower side, is set as an inner surface of the motor arrangement portion **71a**, as illustrated in FIG. 7, a gap is formed between the inner surface of the motor arrangement portion **71a** and the front-side traveling motor **M1**, and the front-side traveling motor **M1** does not contact with the inner surface of the motor arrangement portion **71a** in usual traveling.

(92) The upper structure **3** includes a front-side cross member **93** which is disposed in the vehicle cabin **R1**. The front-side cross member **93** is fixed to an upper surface of the floor panel **70** on a rear side of the motor arrangement portion **71a** and extends in the vehicle width direction. The front-side cross member **93** is formed to be open downward, for example, this open portion is closed by joining the front-side cross member **93** to the upper surface of the floor panel **70**, and a closed cross-section is thereby formed. A left end portion of the front-side cross member **93** is fixed to a right side surface of the left side sill **74**, and a right end portion of the front-side cross member **93** is fixed to a left side surface of the right side sill **75**. As illustrated in FIG. 10, an upper end portion of the front-side cross member **93** is arranged at an equivalent height to an upper end portion of the side sill **75**.

(93) A front portion of the left front seat **S1** is mounted on a left side of a central portion of the front-side cross member **93** in the vehicle width direction, and a front portion of the right front seat **S1** is mounted on a right side of the central portion of the front-side cross member **93** in the vehicle width direction. A slide rail or the like is provided to a lower portion of each of the front seats **S1**, and a front portion of the slide rail is fixed to the front-side cross member **93** via a bracket or the like. Note that a rear portion of the slide rail is fixed to the floor panel **70** on a rear side of the front-side cross member **93**.

(94) The upper structure **3** includes a reinforcement member **94** which couples the motor arrangement portion **71a** and the front-side cross member **93** together. A rear portion of the reinforcement member **94** abuts, from front, a front surface of the front-side cross member **93**, and when a rearward load is exerted on the reinforcement member **94**, the front-side cross member **93** is capable of certainly receiving the load.

(95) The reinforcement member **94** is a member which is arranged in a central portion in the vehicle width direction, supports the motor arrangement portion **71a** from the rear, and thereby inhibits rearward deformation of the motor arrangement portion **71a**. For example, when the front-side traveling motor **M1** is caused to retreat due to an impact load from front and contacts with the motor arrangement portion **71a**, the motor arrangement portion **71a** is apt to deform rearward by receiving the impact load. In such a case, the reinforcement member **94** inhibits deformation of the motor arrangement portion **71a**, and entrance of the front-side traveling motor **M1** into the vehicle cabin **R1** side is thereby inhibited. Further, in usual traveling other than a collision, the motor arrangement portion **71a** is coupled with the highly strong front-side cross member **93**, vehicle-

body rigidity can thereby be improved, and the reinforcement member **94** contributes to an improvement in operation stability and so forth, for example.

(96) The reinforcement member **94** is provided such that its longitudinal direction is directed in the front-rear direction. A dimension of the reinforcement member **94** in the front-rear direction is set longer than a dimension in the left-right direction. Further, a dimension of the reinforcement member **94** in the up-down direction is set shorter than the dimension in the left-right direction, and the reinforcement member **94** as a whole is in a flat shape. In the present embodiment, the reinforcement member **94** is configured with a press-formed component but is not limited to this and may be configured with the extruded material, for example. As illustrated in FIG. 7 and so forth, a rib **94b** extending in the front-rear direction is formed in the reinforcement member **94**.

(97) As illustrated in FIG. 10, a front portion of the reinforcement member **94** is fixed to the upper portion of the motor arrangement portion **71a**. The reinforcement member **94** extends rearward from the upper portion of the motor arrangement portion **71a** and is inclined to be positioned lower toward the rear. Thus, a space is formed between the reinforcement member **94** and the floor panel **70**. Note that the reinforcement member **94** is fixed to a lower portion of the motor arrangement portion **71a**, and in this case, the reinforcement member **94** can extend rearward along the upper surface of the floor panel **70** and can be fixed to the floor panel **70**.

(98) The upper structure **3** includes a floor reinforcement **96** which extends in the front-rear direction below the reinforcement member **94** and along the floor panel **70**. The floor reinforcement **96** is fixed to the upper surface of the floor panel **70**. A rear portion of the floor reinforcement **96** is connected with an intermediate portion of the front-side cross member **93** in the vehicle width direction.

(99) In the present embodiment, as illustrated in FIG. 11 and FIG. 13, a connecting member **95**, which couples the front portion of the reinforcement member **94** and a front portion of the floor reinforcement **96** together in the up-down direction, is provided in the rear of the motor arrangement portion **71a**. The front portion of the reinforcement member **94** and the front portion of the floor reinforcement **96** are fixed to the connecting member **95** by fastening members. The connecting member **95** is formed by shaping a plate material, for example, and is a member which configures a part of the motor arrangement portion **71a**. In other words, the motor arrangement portion **71a** has a main body portion formed with the bulging portion and the connecting member **95**. Note that, not via the connecting member **95**, the front portion of the reinforcement member **94** may directly be fixed to a rear portion of a main body portion of the motor arrangement portion **71a**.

(100) In the present embodiment, because the connecting member **95** serves as a member which configures a part of the motor arrangement portion **71a**, the front portion of the floor reinforcement **96** is connected with the lower portion of the motor arrangement portion **71a**. Accordingly, because the front portion of the floor reinforcement **96** and the front portion of the reinforcement member **94** are respectively connected with portions, which are spaced apart in the up-down direction, of the motor arrangement portion **71a**, rigidity of the motor arrangement portion **71a** can be enhanced in a wide range.

(101) Further, the rear portion of the reinforcement member **94** is connected with a rear portion of the floor reinforcement **96**. Consequently, as illustrated in FIG. 10, a first closed cross-section is configured with the motor arrangement portion **71a**, the reinforcement member **94** which extends rearward from the upper portion of the motor arrangement portion **71a** while being inclined downward, and the floor reinforcement **96** which extends in the front-rear direction. The first closed cross-section is in a triangular shape in a side view, and its dimension in the up-down direction becomes shorter toward the rear.

(102) Further, as illustrated in FIG. 10, the connecting member **95** is formed to extend rearward from an upper-side rear portion of the main body portion of the motor arrangement portion **71a** and to then extend downward. Furthermore, an upper portion of the connecting member **95** is connected

with the upper-side rear portion of the main body portion of the motor arrangement portion **71a**, and a lower portion of the connecting member **95** is connected with a lower-side rear portion of the main body portion of the motor arrangement portion **71a**. Accordingly, a second closed cross-section is configured with the connecting member **95** and the main body portion of the motor arrangement portion **71a** in a side view. The second closed cross-section is in a shape close to a rectangle and is positioned in front of the first closed cross-section. The second closed cross-section is not necessarily required and may be configured in accordance with necessity.

(103) Note that in the above present embodiment, the connecting member **95** is a member which configures a part of the motor arrangement portion **71a**, but this is not restrictive, and the motor arrangement portion **71a** may be configured only with the bulging portion. In this case, the front portion of the reinforcement member **94** is directly fixed to a rear portion of the motor arrangement portion **71a**, and the first closed cross-section is configured with the motor arrangement portion **71a**, the reinforcement member **94**, and the floor reinforcement **96**. Further, the connecting member **95** is fixed to a rear portion of the bulging portion configuring the motor arrangement portion **71a**, and the second closed cross-section is thereby configured with the connecting member **95** and the motor arrangement portion **71a**.

(104) As illustrated in FIG. **12**, the rear portion of the reinforcement member **94** is mounted on the floor panel **70** and the lid body **35** of the battery unit BY. Specifically, a flange **94a** which extends outward in the vehicle width direction is formed in the rear portion of the reinforcement member **94**, and a bolt **B1** passes through the flange **94a**. On an upper surface of the flange **94a**, a nut **N1** into which the bolt **B1** is screwed is fixed. The bolt **B1** passes through a portion directly below the flange **94a** in the lid body **35** and a portion directly below the flange **94a** in the floor panel **70**. The bolt **B1** is caused to pass through the lid body **35**, the floor panel **70**, and the flange **94a** from a portion below the lid body **35** and is screwed into the nut **N1**, and the rear portion of the reinforcement member **94** can thereby be fixed to the floor panel **70** and the lid body **35**. In such a manner, the rear portion of the reinforcement member **94**, the floor panel **70**, and the lid body **35** are fastened together by the shared fastening members **B1** and **N1** and can thus firmly be integrated together. Note that the bolt **B1** may be caused to pass through the flange **94a** from above and may thereby be screwed into the nut **N1** fixed to a lower surface of the lid body **35**. Instead of the bolt **B1**, a screw or the like may be used. Further, plural parts of the reinforcement member **94** which are spaced apart in the vehicle width direction can also be mounted on the lid body **35** and the floor panel **70**.

(105) As illustrated in FIG. **10**, the rear portion of the reinforcement member **94** is also mounted on a central portion of the first inside-casing member **25A** in the vehicle width direction. Specifically, a bolt **B2** passes through a portion of the flange **94a** in the rear portion of the reinforcement member **94**, the portion being spaced apart from the flange **94a** (illustrated in FIG. **12**) in the vehicle width direction. Further, the bolt **B2** also passes through the floor reinforcement **96**, the floor panel **70**, and the lid body **35**. To the rear portion of the reinforcement member **94**, a nut **N2** is fixed so as to agree with a through portion of the bolt **B2**.

(106) An inserting hole **25a** of the bolt **B2** is formed in the first inside-casing member **25A**. The bolt **B2** inserted into the inserting hole **25a** from below is caused to pass through, in order, an upper wall portion of the first inside-casing member **25A**, the lid body **35**, the floor panel **70**, the floor reinforcement **96**, and the rear portion of the reinforcement member **94** and is then screwed into the nut **N2**, and the rear portion of the reinforcement member **94** can thereby also be fastened to the first inside-casing member **25A**. In such a manner, the rear portion of the reinforcement member **94**, the floor reinforcement **96**, the floor panel **70**, the lid body **35**, and the first inside-casing member **25A** are fastened together by the shared fastening members **B2** and **N2** and can thus firmly be integrated together. Note that the bolt **B2** may be caused to pass through the rear portion of the reinforcement member **94** from above and may thereby be screwed into the nut **N2** fixed to the first inside-casing member **25**. Instead of the bolt **B2**, a screw or the like may be used. Further, plural

parts of the reinforcement member **94** which are spaced apart in the vehicle width direction can also be mounted on the first inside-casing member **25A**.

(107) For example, as illustrated in FIG. **3**, the central portion in the first inside-casing member **25A** in the vehicle width direction is an intersecting portion with the front central member **26** and is also an intersecting portion with the first rear central member **27**. The intersecting portion with the front central member **26** (or the first rear central member **27**) in the first inside-casing member **25A** is reinforced by the front central member **26** (or the first rear central member **27**) and is a portion with particularly high strength. On this portion with high strength, the rear portion of the reinforcement member **94** can be mounted.

(108) Further, the rear portion of the reinforcement member **94** may be mounted on the front-side cross member **93**. For example, the rear portion of the reinforcement member **94** may be fixed to an upper portion of the front-side cross member **93** by fastening members, or the rear portion of the reinforcement member **94** may be fixed to the front-side cross member **93** via a bracket.

(109) Based on FIG. **8**, the positional relationship between the reinforcement member **94** and the batteries **B** will be described. When positions of front portions of the batteries **B** disposed foremost among plural batteries **B** included in the battery unit **BY** are compared to a position of the front portion of the reinforcement member **94**, the batteries **B** are arranged such that the front portions of the batteries **B** disposed foremost are positioned in the rear of the front portion of the reinforcement member **94**. Accordingly, an impact load from front in a collision is less likely to be exerted on the batteries **B**.

(110) Further, at least a part of the front-side traveling motor **M1** is positioned so as to overlap with at least the front portion of the reinforcement member **94** in a front view. For example, as illustrated in FIG. **7**, a position of the front-side traveling motor **M1** in the up-down direction is set generally the same as a position of the front portion of the reinforcement member **94** in the up-down direction. Accordingly, when the front-side traveling motor **M1** retreats, its load can certainly be received by the front portion of the reinforcement member **94**.

(111) As illustrated in FIG. **13**, FIG. **15**, and so forth, the upper structure **3** includes a partition wall reinforcement member **98**. The partition wall reinforcement member **98** is provided in front of the motor arrangement portion **71a** in a surface of the upper-side panel portion **71A** on the inside of the vehicle cabin **R1** and extends in the vehicle width direction. A front portion of the partition wall reinforcement member **98** is joined to the lower-side panel portion **71B**. A left end portion of the partition wall reinforcement member **98** is connected with the left suspension tower portion **90**, and a right end portion of the partition wall reinforcement member **98** is connected with the right suspension tower portion **91**.

Working Effects of Embodiments

(112) As described above, because the motor arrangement portion **71a** is formed by causing the lower-side portion of the dash panel **71** to bulge to the inside of the vehicle cabin **R1** and the front-side traveling motor **M1** is arranged in the motor arrangement portion **71a**, it becomes possible to cause the front-side traveling motor **M1** to be close to the rear side. Accordingly, a crash stroke in a collision is sufficiently secured in the front-rear direction.

(113) Next, a description will be made about a collision of the electric vehicle **1** which is configured as described above. In a collision in which an impact load is exerted from front, an obstacle possibly enters the power chamber **R3** which is formed in front of the dash panel **71**, and the obstacle exerts a load in a retreating direction on the front-side traveling motor **M1**. The front-side traveling motor **M1** on which the load in the retreating direction is exerted pushes rearward the motor arrangement portion **71a**. In this case, because the motor arrangement portion **71a** forms the first closed cross-section together with the reinforcement member **94** which is inclined downward toward the rear side and the floor reinforcement **96** and rigidity of the vicinity of the motor arrangement portion **71a** is enhanced, rearward deformation of the motor arrangement portion **71a** is inhibited. In addition, the motor arrangement portion **71a** is supported, from the rear, by the

reinforcement member **94** and the floor reinforcement **96**. Consequently, retreat of the front-side traveling motor **M1** to the inside of the vehicle cabin **R1** is inhibited.

(114) Further, because the front portions of the reinforcement member **94** and of the floor reinforcement **96** can be coupled with each other by the connecting member **95**, rigidity of the vicinity of the motor arrangement portion **71a** can further be enhanced.

(115) Further, because the second closed cross-section other than the above first closed cross-section can be configured with the connecting member **95** and the motor arrangement portion **71a**, rigidity of the vicinity of the motor arrangement portion **71a** can further be enhanced.

(116) The present disclosure is not limited to only the above-described embodiments, which are merely exemplary. It will be appreciated by those skilled in the art that the disclosed systems and/or methods can be embodied in other specific forms without departing from the spirit of the disclosure or essential characteristics thereof. The presently disclosed embodiments are therefore considered to be illustrative and not restrictive. The disclosure is not exhaustive and should not be interpreted as limiting the claimed invention to the specific disclosed embodiments. In view of the present disclosure, one of skill in the art will understand that modifications and variations are possible in light of the above teachings or may be acquired from practicing of the disclosure.

(117) Reference to an element in the singular is not intended to mean “one and only one” unless explicitly so stated, but rather “one or more.” Moreover, where a phrase similar to “at least one of A, B, or C” is used in the claims, it is intended that the phrase be interpreted to mean that A alone may be present in an embodiment, B alone may be present in an embodiment, C alone may be present in an embodiment, or that any combination of the elements A, B and C may be present in a single embodiment; for example, A and B, A and C, B and C, or A and B and C.

(118) No claim element herein is to be construed under the provisions of 35 U.S.C. 112(f) unless the element is expressly recited using the phrase “means for.” As used herein, the terms “comprises,” “comprising,” or any other variation thereof, are intended to cover a non-exclusive inclusion, such that a process, method, article, or apparatus that comprises a list of elements does not include only those elements but may include other elements not expressly listed or inherent to such process, method, article, or apparatus.

(119) The scope of the invention is indicated by the appended claims, rather than the foregoing description.

INDUSTRIAL APPLICABILITY

(120) As described in the foregoing, a vehicle-body front structure according to the present disclosure can be provided to an electric vehicle, for example.

REFERENCE SIGNS LIST

(121) **1** electric vehicle **10** battery casing **32** front-side battery frame **70** floor panel **71** dash panel (partition wall portion) **71a** motor arrangement portion **93** front-side cross member **94** reinforcement member **95** connecting member **96** floor reinforcement A vehicle-body front structure B battery **M1** traveling motor

Claims

1. A vehicle-body front structure for an electric vehicle in which a traveling motor is installed in a vehicle front portion, the vehicle-body front structure comprising: a partition wall portion which extends in a vehicle width direction in the vehicle front portion and demarcates a vehicle cabin inside space from a power chamber; a motor arrangement portion formed by a part of the partition wall portion that bulges toward the vehicle cabin inside space, and at least a part of the traveling motor installed on outside of the vehicle cabin inside space is capable of being arranged in the motor arrangement portion; a reinforcement structure which extends from an upper portion of the motor arrangement portion towards a vehicle rear wherein the reinforcement structure is inclined so that a rear portion of the reinforcement structure is positioned lower in an up-down direction of the

- vehicle toward the vehicle rear; and a floor reinforcement which extends in a vehicle front-rear direction below the reinforcement structure and along a floor panel, wherein a first closed cross-section shape is formed by coupling together the motor arrangement portion, the reinforcement structure, and the floor reinforcement in order to enhance rigidity of the motor arrangement portion.
2. The vehicle-body front structure according to claim 1, wherein a connecting structure, which couples together a front portion of the reinforcement structure and a front portion of the floor reinforcement in the up-down direction of the vehicle, is provided in the vehicle rear of the motor arrangement portion.
 3. The vehicle-body front structure according to claim 2, wherein a second closed cross-section shape is formed by coupling the connecting structure and the motor arrangement portion.
 4. A vehicle-body front structure according to claim 3, comprising a cross structure which is fixed to the floor panel on a vehicle rear side of the motor arrangement portion and extends in the vehicle width direction, wherein a rear portion of the floor reinforcement is connected with an intermediate portion of the cross structure in the vehicle width direction.
 5. The vehicle-body front structure according to claim 4, wherein a front portion of the floor reinforcement is connected with a lower portion of the motor arrangement portion.
 6. The vehicle-body front structure according to claim 1, comprising a cross structure which is fixed to the floor panel on a vehicle rear side of the motor arrangement portion and extends in the vehicle width direction, wherein a rear portion of the floor reinforcement is connected with an intermediate portion of the cross structure in the vehicle width direction.
 7. The vehicle-body front structure according to claim 1, wherein a front portion of the floor reinforcement is connected with a lower portion of the motor arrangement portion.
 8. The vehicle-body front structure according to claim 2, comprising a cross structure which is fixed to the floor panel on a vehicle rear side of the motor arrangement portion and extends in the vehicle width direction, wherein a rear portion of the floor reinforcement is connected with an intermediate portion of the cross structure in the vehicle width direction.
 9. The vehicle-body front structure according to claim 2, wherein a front portion of the floor reinforcement is connected with a lower portion of the motor arrangement portion.
 10. The vehicle-body front structure according to claim 3, wherein a front portion of the floor reinforcement is connected with a lower portion of the motor arrangement portion.
-
