ENGINE ACCESS PANELS

Abstract

A recreational off-highway vehicle includes side-by-side passenger and driver seats held within a chassis. The seats sit low in the chassis and are covered by a roll cage. Grab handles are positioned on the sides of the passenger seat. Select large round tubing protects the vehicle, while rectangular tubing frames the portions of the vehicle beneath body panels. The vehicle is powered by an engine rearward of the seats that is connected to a transaxle. A radiator is positioned above the engine. A cover with an access panel is situated between the engine and the passenger seats. The vehicle is suited for rough terrain travel.

Background/Summary

PRIORITY CLAIM [0001] This present application is a continuation of U.S. application Ser. No. 18/752,674, entitled ENGINE ACCESS PANELS FOR OFF-HIGHWAY VEHICLE filed Jun. 24, 2024; which is a continuation of U.S. application Ser. No. 18/385,037 entitled OFF-ROAD VEHICLE filed Oct. 30, 2023 and issued as U.S. Pat. No. 12,054,211; which is a continuation of U.S. application Ser. No. 18/090,891 entitled OFF-ROAD VEHICLE RADIATOR filed Dec. 29, 2022 and issued as U.S. Pat. No. 11,932,333; which is a continuation of U.S. application Ser. No. 17/700,352 entitled OFF-HIGHWAY RECREATIONAL VEHICLE filed Mar. 21, 2022 and issued as U.S. Pat. No. 11,648,998; which is a continuation of U.S. application Ser. No. 17/174,262 entitled VEHICLE ENGINE MOUNTING filed Feb. 11, 2021 and issued as U.S. Pat. No. 11,279,423; which is a continuation of U.S. application Ser. No. 16/664,597 entitled OFF-HIGHWAY RECREATIONAL VEHICLE filed Oct. 25, 2019 and issued as U.S. Pat. No. 10,933,932; which is a continuation of U.S. application Ser. Nos. 16/223,743 entitled OFF-HIGHWAY RECREATIONAL VEHICLE, filed Dec. 18, 2018 and issued as U.S. Pat. No. 10,723,397, and 16/224,308 entitled OFF-HIGHWAY RECREATIONAL VEHICLE, filed Dec. 18, 2018 and issued as U.S. Pat. No. 10,723,398-which both are continuations of U.S. application Ser. No. 15/905,321 entitled OFF-HIGHWAY RECREATIONAL VEHICLE filed Feb. 26, 2018, and issued as U.S. Pat. No. 10,239,571; which is a continuation of U.S. application Ser. No. 15/684,863 entitled OFF-HIGHWAY RECREATIONAL VEHICLE filed Aug. 23, 2017 and now abandoned; which is a continuation of U.S. application Ser. No. 15/143,353 entitled OFF-HIGHWAY

RECREATIONAL VEHICLE filed Apr. 29, 2016 and issued as U.S. Pat. No. 9,771,112; which is a divisional of U.S. application Ser. No. 13/775,133 entitled OFF-HIGHWAY RECREATIONAL VEHICLE filed Feb. 23, 2013 and issued as U.S. Pat. No. 9,327,587; which is a continuation-in-part of U.S. application Ser. No. 13/485,696 entitled VEHICLE CONFIGURATION filed May 31, 2012 and issued as U.S. Pat. No. 9,180,801, the contents of which are incorporated herein by reference in their entirety.

FIELD OF THE DISCLOSURE

[0002] The present invention relates to side-by-side, recreational off-highway vehicles, their configurations, chassis, suspension, and ergonomics.

BACKGROUND

[0003] Side-by-side recreational off-highway vehicles (“ROVs”) are quite capable in a wide variety of riding environments and situations, whether for sport or utility purposes. The ability of the vehicles to carry multiple occupants in a side-by-side seating arrangement makes them socially enjoyable to ride as well. The vehicles can be easy to enter and exit and easy to operate with controls and ergonomics somewhat similar to automobiles. However, unlike most automobiles, ROVs can be driven on harsh off-road terrain. The extent to which such terrain can be accessed depends on multiple factors, including the vehicle width, suspension, turning radius, under-carriage clearance, wheelbase, center of gravity, and power. The arrangement of these aspects and their interrelations can be important in determining the occupant ride characteristics, reliability, ease of maintenance, and terrain and cargo capabilities of the ROV.

SUMMARY

[0004] The present invention provides a side-by-side recreational off-highway vehicle having two front wheels and at least two rear wheels. The vehicle includes a chassis, an engine, a transmission, a drive unit, and body panels. The chassis includes a front portion, a middle portion, and a rear portion. The front portion is coupled to the front wheels. The middle portion is coupled to the rear wheels and surrounds an occupant compartment having at least two side-by-side seats for a driver and at least one passenger. The chassis includes frame members of rectangular cross section and frame members of generally circular or oval cross section.

[0005] The engine is secured to the rear portion of the chassis. The transmission is secured to the engine. The drive unit is operably coupled to the driven clutch, and drivingly coupled to the rear wheels.

[0006] The body panels are secured to the chassis and cover most of the frame members of rectangular cross section while leaving exposed many of the frame members of generally circular or oval cross section. A frame member of generally circular cross section extends along right and left lower edges of the middle portion of the chassis. Frame members of generally circular cross section form a roll cage above at least the middle portion of the chassis. The vehicle further includes right and left doors in the middle portion of the chassis. The frame members along the right and left lower edges are positioned below the doors. The frame members of generally circular cross section are also exposed below the roll cage at a forward portion of the middle portion of the chassis.

[0007] The vehicle also includes a rear cargo box positioned above the drive unit. The rear cargo box has an opening covered with a movable door generally above the engine to access engine components. A separate body panel extends forward of the cargo box and forward of left rear wheel, between the left rear wheel and the driver door. The separate body panel includes an opening allowing air passage to an air intake conduit and an airbox for providing combustion air to the engine.

[0008] The transmission includes a continuously variable transmission (CVT) with a cooling air intake having a conduit also extending from the opening in the body panel.

[0009] The body panels include at least one bridging body panel extending from the cargo box to

between the engine and the seats. A rear separation panel extends downwardly from the bridging body panel to proximate a floor of the vehicle between the occupant compartment and the engine. The rear separation panel is formed of at least one separate panel secured to the bridging body panel. It further includes a removable portion adjacent an engine component, such as an oil filter and dipstick.

[0010] The drive unit includes a transaxle fastened to the engine, the drive clutch being driven by the engine and the driven clutch driving the transaxle. The engine and transaxle are mounted to the chassis with vibration isolation members. The airbox, throttle body, and CVT are secured to the engine and transaxle so as to move with the engine and transaxle relative to the chassis. The engine and transaxle form an assembly that bridges from the member mounting the engine to the member mounting the transaxle. The engine is forward of the transaxle, with a front driveline extending forward from the transaxle and extending under the engine.

[0011] The middle portion of the chassis has a distance from its underside to the ground defining a ground clearance, the driver seat and the passenger seat each having an upwardly facing lower seating surface upon which an occupant rests and a seat back for the back of the occupant to lean against; wherein the vertical distance between a lowest portion of the lower seating surface and the underside of the middle portion of the chassis is less than the ground clearance of the middle portion of the chassis when not vehicle is not loaded.

[0012] The wheelbase of the vehicle is at least 80 inches and preferably approximately 83 inches. The driver seat includes a seat index point, the seat index point being within 16 inches of the underside of the middle portion of the chassis. The seat index point is preferably positioned longitudinally between a center of the wheelbase and a center of gravity of the vehicle.

[0013] The vehicle further includes a driver door and a passenger door. The driver door and the passenger door each have a rear pivot and a front latch. The rear pivots also have a downward angle, such that the doors swing rearwardly and downwardly when opening.

[0014] The passenger door includes an interior grab member forward of the passenger seat back. It is secured to an interior facing side of the passenger door with the grab member being positioned longitudinally near a forward-most portion of the passenger lower seating surface. A medial passenger grab member is secured to the chassis on the medial side of the passenger seat longitudinally near the forward-most portion of the passenger lower seating surface. The vehicle includes a transmission shift lever to the left of the passenger grab bar such that the grab bar is situated laterally between the passenger seat and the shift lever.

[0015] The vehicle includes a floorboard with an integrally molded upwardly angled footrest forward of the passenger seat. The driver floorboard includes a heel step between the driver seat and the throttle pedal. A cup holder is also integrally molded with the floorboard.

[0016] The rear suspension is coupled between the chassis rearward portion and the rear wheels and includes right and left suspension arms and right and left shock absorbers. A rear sway bar is coupled between the right and left suspension arms. The sway bar extends rearwardly from the arms and mounts to the rearward-most end of the chassis rearward portion. The mounts are rearward of the shock absorbers.

[0017] The distance between the driver seat and the passenger seat is greater than the distance between the driver seat and the driver door and the distance between the passenger seat and the passenger door. Preferably, the distance between the seats is at least twice the distance between the passenger door and the passenger seat.

[0018] Further with regard to the engine and transmission arrangement, a forward end of the engine is mounted to the chassis and a rearward portion of the transmission is coupled to the chassis, the engine and transmission bridging from a forward engine mounting location to a rearward transmission mounting location. The engine is mounted to the chassis with at least one vibration isolation member and the transmission is mounted to the chassis with at least one vibration isolation member. A first mounting plate is fastened to the engine and to the transmission to secure

the engine and transmission together. A second mounting plate is fastened directly to the transmission and fastened to the first mounting plate. The CVT has a drive clutch engaged with the engine and a driven clutch engaged with the transmission. The CVT is not rigidly mounted directly to the chassis. The engine, transmission, CVT, throttle body, and airbox are vibration isolated together relative to the chassis.

[0019] The airbox includes an air outlet and the engine includes an air inlet. The airbox air outlet is substantially in line with the throttle body and the engine air inlet. Furthermore, the distance from the airbox air outlet and the engine air inlet is less than a distance from a front end of the engine to a rear end of the transmission. A forward-extending driveshaft extends from a bottom end of the transmission beneath the engine toward the front wheels.

[0020] A method for assembling a vehicle is also provided. An engine is secured rigidly to a transmission to form an engine and transmission assembly. The assembly is moved through the mid chassis portion and through a front end of the rear chassis portion to within the rear chassis portion. The engine and transmission assembly are then secured within the rear chassis portion. The CVT is secured to the engine and transmission after securing the engine to the transmission and before moving the assembly to within the rear chassis portion.

[0021] At the front of the vehicle, right and left headlights are secured to a front end of the chassis forward portion. A radiator is secured within a front end of the chassis forward portion directly between the headlights. The chassis forward portion also includes front frame members and right and left bumper bars removably fastened to the front of the front frame members. The radiator is positioned between the front frame members and the bumper bars. The right and left headlights are positioned outwardly of the right and left bumper bars respectively. A winch is mounted below the radiator.

[0022] A fuel tank is secured by the chassis middle portion at least partially beneath the passenger seat. The fuel tank extends beneath and behind the lower seating portion, the tank having a height that increases behind the lower seating portion relative to the portion of the tank directly beneath the lower seating portion. A fuel pump is secured to the portion of the fuel tank behind the lower seating portion. The chassis includes a frame member beneath the passenger seat and on top of the fuel tank. The fuel tank includes a lower edge having a recess, the recess nesting with a lower chassis frame member. The fuel tank includes a corner recess into which a battery is positioned. The chassis further includes a battery tray adjacent the corner recess in the fuel tank.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0023] Preferred and alternative examples of the present invention are described in detail below with reference to the following drawings:

[0024] FIGS. 1A-D are isometric views of the vehicle of the present invention;

[0025] FIGS. 2A-B are isometric views of the chassis of the vehicle shown in FIGS. 1A-D;

[0026] FIGS. 3A-C are top and side views of the body panels of the vehicle shown in FIGS. 1A-D;

[0027] FIG. 3D is an isometric view of a portion of the vehicle of the present invention with the hood and dash removed;

[0028] FIGS. 4A-D are isometric views into the occupant cabin of the vehicle;

[0029] FIG. 4E is a side-elevational view of a portion of the vehicle illustrating passenger seating;

[0030] FIG. 5A is an isometric view of an access panel in position with the vehicle;

[0031] FIG. 5B is a view with the panel of FIG. 5A removed;

[0032] FIG. 5C is an isometric view of the panel of FIG. 5A;

[0033] FIG. 6 is an isometric view of the front suspension of the vehicle of the present invention;

[0034] FIGS. 7A-C are isometric views of the rear suspension of the vehicle;

[0035] FIG. 8A is a side-elevational view of the engine and transaxle in place in the chassis of the vehicle;

[0036] FIG. 8B is an isometric partially exploded view of the engine and transaxle assembly;

[0037] FIG. 8C is an isometric view of the engine mounting location in the chassis;

[0038] FIG. 8D is a top view of the engine and transaxle assembly of the present invention;

[0039] FIG. 9A is a rear isometric view of the air intake assembly installed with the engine;

[0040] FIG. 9B is a side-elevational view of the engine, transaxle, and air intake tract of the present invention;

[0041] FIG. 9C is a close-up isometric view of the airbox mounting;

[0042] FIG. 9D is a right side-elevational view of the airbox to engine path;

[0043] FIG. 9E is an isometric view of the air intake assembly of the present invention;

[0044] FIGS. 9F-G are rear views inside the airbox;

[0045] FIG. 10A is a front isometric view of the front of the vehicle with the body panels removed;

[0046] FIG. 10B is a top view of the front of the vehicle with the body panels removed;

[0047] FIG. 10C is a side-elevational view of the front of the vehicle with the body panels and headlights removed;

[0048] FIG. 11A is a side-elevational view of the fuel tank within the chassis of the vehicle; and

[0049] FIGS. 11B-C are isometric views of the fuel tank of FIG. 11A.

[0050] FIG. 12 is a schematic side view of a vehicle having a center of mass at least approximately superimposed in at least the longitudinal and vertical directions with the center of mass of the passenger according to embodiments of the present invention.

[0051] FIG. 13 is a schematic view of a seat of the vehicle of FIG. 12 according to embodiments of the present invention.

DETAILED DESCRIPTION

[0052] As shown in the drawings listed above, the invention is a vehicle that includes side-by-side seating for a driver and a passenger (“occupants”). The vehicle is preferably less than about 50 inches wide such that it can access trails developed and designated for all-terrain vehicles (ATVs). Thus, as shown in FIG. 1A, a vehicle 10 includes a chassis 12, a driver seat 14, a passenger seat 16, and a steering wheel 18 forward of the driver seat 14. The chassis 12 supports the vehicle components including the seats 14, 16. In alternate embodiments, additional seating may be provided rearward of the driver and passenger seats 14, 16.

[0053] The chassis also supports a roll cage 20, safety nets 22, and body panels 24. The chassis is constructed with rectangular metal tubing as well as round (or somewhat round) tubing, referring to the cross-sectional shape of the tubing. Generally, the rectangular tubing is hidden by the body panels 24, whereas most of the outwardly visible tubing is the round tubing. The round tubing is strong for perimeter support and has a desirable appearance that may signify off-road ability to some users. The round tubing is able to provide impact protection in strategic locations as well, such as along the bottom edge of the vehicle, the front and rear of the vehicle, and for the roll cage. The square tubing is advantageous for inner chassis support as it can be used to secure vehicle components without the need for as many tabs fixed to the chassis. Items can be secured to the rectangular tubing sides, such as by a simple weld or a fastener.

[0054] The vehicle 10 also includes a prime mover, preferably a gas-powered engine 26. The engine is held by the chassis 12. The engine is drivingly coupled to a pair of front wheels 28, having front tires 30 mounted thereon, the front wheels 28 being held to the chassis 12 with a front suspension 32. The engine is also drivingly coupled to a pair of rear wheels 34, having rear tires 36 mounted thereon, the rear wheels 34 being held to the chassis 12 with a rear suspension 38. Front and rear suspensions 32, 38 will be described in more detail below in connection with FIGS. 6 and 7.

[0055] FIG. 1B also illustrates a general outer view of the vehicle 10. Front-opening driver and passenger doors 40, 42 are provided for ingress and egress to the occupant cabin having the seats

14, 16. The doors **40, 42** are constructed with door frames **44** that are hinged at the rear to the chassis and latched at the front to the chassis. Door panels **46** are preferably secured to the door frames **44**. Door panels **46** cover the outside of the door frames **44**, provide a pleasing external appearance and help to safely secure the occupants in the vehicle **10**. Note that door frames **44** and door panels **46** do not extend vertically over the entire access opening on the side of the vehicle. The nets **22** help to cover some of the space, while allowing the vehicle to feel open and provide good visibility for the occupants in the generally off-highway terrain to which the vehicle is suited. Alternatively, nets **22** may be replaced with other structure or support to protect the driver and passenger while still allowing good visibility.

[0056] Spaced below the door panels **46** are foot panels **48**. Foot panels **48** cover a lower portion of the chassis **12** and aid in keeping the occupants' feet and legs within the vehicle **10**. Panels extending forward of the foot panels provide front fenders **50**, arching over the front tires **30**. Left and right-side panels **52, 54**, extend above and behind foot panels **48**. Side panels **52, 54** are secured to the chassis **12** rearward of the door panels **46**. The space between side panels **52, 54**, foot panels **48** and front fenders **50** is the access opening in the side of the vehicle **10**. This opening is selectively closed by the doors **40, 42**.

[0057] The front of the vehicle **10** is also shown in FIG. **1B**. A hood panel **56** extends between the upper portions of front fenders **50** to cover a top front portion of the chassis **12**. A grill panel **58** extends downwardly from the front of the hood panel **56**. A bumper panel **60** is situated at the lower end of the grill panel **58** and may be an integral extension thereof. An opening may be formed in the bumper panel **60** to accommodate a winch **62** at the front of the vehicle **10**. A pair of headlights **64** are preferably secured to the chassis **12** on either side of the grill panel **58**, beneath the forward-most portion of front fenders **50**.

[0058] The rear outer aspects of the vehicle are shown in FIG. **1C**. A rear cargo box **66** is provided rearward of the seats **14, 16**. Rear fenders **68** extend on either side of the cargo box **66**. The rear fenders **68** extend forward from the box to the side panels **52, 54**. Fenders **68** extend downwardly partially along the rearward edges of the side panels **52, 54**. Taillights **70** are secured to a rear grill that is in turn attached to the cargo box **66**. Taillights **70** preferably include running lights and braking lights. They may alternatively include backup lights and/or turn signals.

[0059] A head panel **72** bridges the space between the cargo box **66** and the occupant cabin. The head panel includes an upper engine access door **74**. This door preferably provides access to the top of the cylinder head (the valve cover and spark plugs) of the engine **26**. Thus, minor maintenance tasks can be performed on the engine without removal of the head panel **72** and cargo box **66**. The access door **74** is preferably secured closed with fasteners on its lower corners.

[0060] Within the occupant cabin a dashboard **76** is positioned forward of the seats **14, 16** and steering wheel **18**. The dashboard **76** extends rearwardly from hood **56** and front fenders **50**. The dashboard **76** includes openings for the steering column and the instrument gauge. In standard fashion it allows room beneath for the occupant's legs. A floorboard **78** is also seen in FIG. **1C** beneath the dashboard. A passenger area front panel **80** extends between the floorboard **78** and the dashboard **76**. Completing the occupant envelope is a passenger area rear panel **82** shown in FIG. **1B**. The rear panel **82** extends behind the seats between the floorboard **78** and the head panel **72**. These panels are preferably constructed of molded plastic. They are secured to the chassis **12** with fasteners.

[0061] Portions of the drive system of vehicle **10** are shown in FIG. **1C**. A transaxle **84** is positioned rearward of engine **26**. The transaxle **84** includes the transmission gears and rear gearcase to drive the rear axles. A continuously variable transmission (CVT **86**) is positioned on the left side of the engine **26** and transaxle **84** and spans between the two to provide power from the engine **26** to the transaxle **84**. The airbox **88** is also visible on the rear of the vehicle **10**. The airbox **88** being positioned at the rear end of the vehicle, it is easily accessible for maintenance.

[0062] The left side of the vehicle **10** includes an air intake opening **90** within the left side panel

52. An engine air intake duct **92** and a CVT air intake duct **94** both extend from this opening **90**, to the airbox **88** and the CVT **86**, respectively.

[0063] FIG. 1D illustrates some of the components from the rear right side of the vehicle **10**. A fuel fill opening **96** is provided with the right side panel **54**. A glove box **98** is recessed into the dashboard **76**. An instrument gauge **100** is secured in the dashboard **76** preferably between the glove box **98** and the steering wheel **18**. A receiver hitch **102** is provided extending from the rearward-most portion of the chassis **12**, rearward of the transaxle **84**.

[0064] Details of the chassis **12** are seen in FIGS. 2A and 2B. The chassis **12** includes a chassis front portion **104**, a chassis mid portion **106**, and a chassis rear portion **108**. The front portion **104** secures the front suspension **32**, the steering mechanism (not shown), and the winch **62**. It also supports other components, such as headlights, a radiator, electrical lines, and hoses discussed in more detail below. The mid portion **106** secures the occupant area and related components of the vehicle **10**. The rear portion **108** secures the rear suspension **38**, the engine **26**, and the transaxle **84**.

[0065] More specifically the chassis front portion **104** includes front bars **110**, front support frame **112**, bumper bars **114**, and various brackets **116**. Front bars **110** are round tubular frame pieces welded together and extending along the front of the chassis **12**, curving slightly outwardly from top to bottom. The front bars **110** are bolstered behind by the front support frame **112**. Bumper bars **114** are fastened to front bars **110** forward of front bars **110**. As discussed below, bumper bars **114** provide securement and protection for the radiator and help secure the lights and winch **62**.

[0066] The chassis mid portion **106** includes undercarriage frame members **118** that are secured at their forward end to the chassis front portion **104**. Preferably the undercarriage frame members are tubes with rectangular cross sections welded together, except for an outer lower rail **120** that has a larger, round cross section. Lower rail **120** extends along the lower sides of the chassis mid portion **106** to protect the chassis from impacts. As seen in FIGS. 1A-D, the lower rail **120** is visible below the body panels **24** (including foot panels **48**), whereas the remainder of the undercarriage frame is generally hidden from view. Lower rail **120** extends on each side of vehicle **10** from the rear of chassis mid portion **106** then bending medially to connect to the narrower chassis front portion **104**. Impact with dirt, rocks, logs, or other terrain may be more common along the portion of the chassis **12** formed by the lower rail **120**. It's larger, round cross section is well suited to protect the remainder of the vehicle. The remainder of undercarriage frame **118** is preferably welded directly to the inner sides of lower rail **120**.

[0067] Rising up from undercarriage frame **118** near the bend in lower rail **120** is a front frame member **122** on each side of chassis **12**. Front frame members **122** rise upwardly and forwardly to meet a dash bar **124**. Dash bar **124** extends across the front of chassis mid portion **106** and is also connected to the tops of front bars **110** inboard of the connections to front frame members **122**. Dash bar **124** is also preferably of larger, round cross-sectional shape. After connecting with front frame members **122**, the dash bar **124** bends upwardly and rearwardly to connect to the roll cage **20**.

[0068] At the rear ends of lower rails **120**, rear frame members **126** extend upwardly, defining the rear corners of chassis mid portion **106**. These frame members, rectangular in cross section, extend upwardly and slightly rearwardly to a connection with a head bar **128** and the rearward end of the roll cage **20**. Head bar **128** extends from one side of the rear of the chassis mid portion **106** to the other. Head bar **128** and the rear frame members **126** frame the upper and sides of a chassis opening into which the engine and transaxle are preferably inserted. These chassis members form the rear structural support for the vehicle.

[0069] Additional support frame members are provided in the chassis mid portion **106**. Side support members **130** extend between rear frame members **126** and front frame members **122** on each side of the chassis mid portion **106**. Side support members **130** also secure a seat support frame **132** in place. Seat support frame **132** extends across chassis mid portion **106** from one side to the other and includes securement brackets for seats **14**, **16**. Seat support frame **132** is preferably

constructed of two separate weldments-a front weldment and a rear weldment. The front weldment is secured to the rear weldment with longitudinally extending channels between the two. A passenger grip **134** is also fastened to the seat support frame **132**. The passenger grip **134** extends upwardly and forwardly from a front mid portion of the seat support frame **132**. As will be discussed below, the passenger grip **134** extends upwardly on the medial side of the passenger seating area.

[0070] FIG. 2B better illustrates the rear frame members of chassis rear portion **108**. Chassis rear portion **108** includes rear lower frame members **136** along the bottom of the chassis rear portion **108** and rear upper frame members **138** along the top of the chassis rear portion **108**. Rear tubes **140** extend from the upper frame members **138** to the lower frame members **136** at the rearward end of the chassis **12**. In the preferred embodiment, rear tubes **140** extend continuously into lower frame members **136**. Rear tubes **140** preferably are constructed of round cross-sectional tubing. Further rear framing is provided with rear support members **142** extending between lower frame members **136** and upper frame members **138**. These members provide additional structural support and mounting locations for vehicle components, such as the engine **26**, the transaxle **84**, the rear suspension **38**, and the cargo box **66**.

[0071] The chassis rear portion **108** also includes lower rearward supports **144** that triangulate the connection between the chassis mid portion **106** and the chassis rear portion **108**. Rearward supports **144** extend from the rearward ends of lower rails **120** to the rear lower frame members **136**. These supports also provide securement for engine front mounts **146** in the forward end of the chassis rear portion **108**. Transaxle rear mounts are also provided; they are secured to the rear support members at the rearward end of the chassis rear portion **108**. The engine and transaxle mounts will be shown in more detail in connection with the engine and transaxle discussed below.

[0072] Also shown in FIG. 2B are tube couplers **150** welded between the rear frame members **126** and the head tube **128**. These couplers also provide securement to the roll cage **120**.

[0073] FIGS. 3A through 3D illustrate the body panels **24** that are secured to the chassis **12**. Several of the panels have already been mentioned. FIGS. 3A and 3B show in more detail several features of the vehicle occupant cabin. Floorboard **78** includes cup holders **152** molded integrally therewith. Floorboard **78** is preferably molded in a single piece. However, it may alternatively be molded in two parts-a driver side and a passenger side, each with cup holders **152**, as well as a driver footrest **156** and a passenger footrest **154**. The footrests are "dead pedals" that the occupants can use for resting a foot or bracing themselves within the vehicle **10**. The footrests **154**, **156** are also preferably integrally molded with the floor panels.

[0074] Additional body panels **24** are within the vehicle cabin including an engine cover **158**, a center console **160**, a battery cover **162**, and a lower engine access panel **164**. Rear panel **82** is formed in two parts-a right side and a left side. The engine cover **158** is formed of a right and a left part, fastened down the middle. The two outer sides extend from the two sides of passenger area rear panels **82** and are attached thereto. The center console **160** is a raised hump between the seats that accommodates the driveline, the shift cable, cooling hoses, and the electrical harness. An opening in the top of the center console **160** allows for movement of the shift lever. The lower engine access panel **164** is held on the forward end of the engine cover and allows access to the oil filter and dipstick, as will be shown in more detail below.

[0075] An upper engine cover **166** is also provided at the rear of the head panel **72** within the cargo box **66**. Upper engine cover **166** extends integrally from head panel **72**. It includes the upper engine access door **74**, mentioned above.

[0076] FIG. 3C illustrates the right side of the body panels. A fuel fill recess **168** is shown in the right-side panel **54**. The forward extent of the passenger area front panel **80** is also well shown here, as well as the rearward extent of the passenger area rear panel **82**.

[0077] FIG. 3D provides a close-up view of the body panels **24** secured on the chassis over numerous vehicle components. A radiator **170** is positioned rearward of the grill panel and between

headlight assemblies **64** on the right and left sides of the radiator **170**. The headlight assemblies extend between the front fenders **50** and the grill panel on either side of the upper end of the radiator **170**. With regard to the chassis **12**, the radiator is situated between the bumper bars **114** and the front support frame **112** (see FIG. 2A).

[0078] Also shown among other components is a brake reservoir **174**, which is accessible under the hood panel **56**. Several components are accessible under the hood panel **56**, including the radiator **170**, the headlight assemblies **172**, a steering assembly **176**, and portions of the front suspension **32**. Above the hood and other body panels, roll cage couplers are provided at the upper ends of the dash bar **124**. Note that storage space **180** is also provided under the hood panel **56**. A bin or other member may be advantageously provided under the hood for this purpose. As several components along with storage space **180** may be accessed under the hood panel **56**, hand fasteners are preferably provided to secure hood panel **56** in place.

[0079] FIGS. 4A-D illustrate various ergonomic aspects of the vehicle **10**. The vehicle occupant cabin is shown with the seats **14**, **16**, floorboard **78**, doors **40**, **42**, and controls including the steering wheel **18**. The doors include door latches **182** that may be opened from the outside of front of the rearwardly opening doors. The doors **40**, **42** are hinged at a slight angle such that they swing outwardly and downwardly. Thus, they stay open due to gravity until closed. Nets **22** or other structure may be secured to the top and bottoms of the rearward ends of the doors **40**, **42** to provide additional protection to the occupants. In place of nets, additional structure may be provided to provide impact protection and securement within the cabin.

[0080] The door frames **44** include upper and lower bars over which the door panels **46** are secured. An interior passenger door hand hold **184** extends from the upper bar to the lower bar on the passenger door frame **44** above and to the right of the front of the passenger seat **16**. Door hand hold **184** is angled forwardly as it extends upwardly so as to provide a comfortable grip to the occupants.

[0081] In the case of the passenger door handle, it provides a convenient place for the passenger to grasp when riding to steady himself or herself as the vehicle **10** moves. The passenger may comfortably grasp the door handle **184** with the right hand and the passenger grab bar or grip **134** with the left hand. The handle **184** and bar **134** are located at the forward end of the seating area at nearly the same longitudinal location along the vehicle **10**. The grab bar **134** also helps to separate the passenger from interfering with the operation of the vehicle. For example, the bar **134** separates the passenger from a shift lever **188**. Thus, the passenger's leg will not bump the shift lever **188** that extends up through the center console **100**. The grab bar is preferably a bar of round cross section with a rubber grip on the upper end thereof. The door handles **184**, **186** may also have rubber grips.

[0082] A throttle pedal **190** and a brake pedal **192** are also accessible to the driver seated in the driver seat **14**. As the preferred embodiment of the vehicle utilizes a CVT, a clutch pedal is not shown, although can be provided in alternate embodiments. The pedals **190**, **192** are forward of and slightly above a heel rest **194**. Heel rest **194** is provided in the floorboard **78** as an angled face providing a step for locating the heel of the driver by feel. This allows the driver to easily place his or her foot at the proper location to operate the vehicle **10** even while traversing rough terrain. Undercarriage frame **118** may extend behind the floorboard **78** adjacent the underside of heel rest **194** to provide additional support. The floorboard rearward of heel rest **194** may be sloped to provide for the step of heel rest **194**. Heel rest **194** extends between driver footrest **156** and a floorboard hump. It also extends on the passenger side of floorboard **78** between the passenger footrest **154** and floorboard hump **196**. Floorboard hump **196** houses a portion of the driveline, hoses, and electrical wires.

[0083] FIGS. 4A and 4E show the position of the upper and lower door hinges **198**, **200**. The hinges are secured between the side support members **130** and the door frame **44** on each door. The hinges may be any member allowing pivotal movement between the door **40** and the chassis **12**. As discussed above, the hinge axis is tilted rearwardly in the preferred embodiment illustrated, such

that the door swings rearwardly and downwardly when opening.

[0084] FIG. 4A also shows some detail of the head panel **72** that extends over the head bar **128** rearward of the seats **14**, **16**. Head panel **72** bridges the space between the cargo box **66** and the passenger area rear panel **82**. Head panel **72** includes raised portions rearward of the tops of the seats **14**, **16** with a recess between the raised portions for rearward visibility.

[0085] The arrangement of the vehicle **10** provides a low center of gravity and places the driver and passenger low in the vehicle near the center of gravity of the vehicle. This helps improve the stability and ride quality of the occupants over rough terrain. Extending the wheel base to over 80 inches, preferably about 83 inches also aids in the stability of the vehicle and allows the positioning of the seats **14**, **16** lower in the chassis **12**.

[0086] FIGS. 5A-C illustrate the lower engine access panel **164** that is rearward of and laterally between the seats **14**, **16** in the vehicle cabin. A panel fastener **202** secures the access panel to the rearward end of the center console **160**. The fastener **202** employs a tab that may be turned by hand to remove the panel. The shape of the access panel **164** continues the shape of the center console **160** and transitions to the shape of the engine cover **158** as the access panel **164** extends rearwardly.

[0087] With the lower engine access panel **164** removed, an oil filter **204** and dipstick **206** may be accessed as shown in FIG. 5B. As shown in FIG. 5C, the access panel **164** includes a fastener recess **207** in which the panel fastener is placed. Securement tabs **208** extend from the sides of the panel to engage the surrounding engine cover **158**. Once the fastener **202** is secure the tabs also secure the access panel **164** in place. This allows access to engine parts without difficult and timely disassembly of vehicle components.

[0088] FIG. 6 illustrates the front suspension **32** of vehicle **10**. It also shows in some detail the chassis front portion **104**. The front suspension is constructed of right and left four-bar linkages each side including the chassis, the upper arm **212**, the lower front A-arm **214**, and the knuckle assembly **216**. The exact angles, lengths, and spacing of the connections between the links is selected to determine the travel of the wheel connected to a hub **218** attached to the knuckle assembly **216**.

[0089] Steering rods **220** are coupled between the steering assembly (not shown) and the knuckle assembly **216**. Right and left "half shaft" front axles also move with the suspension, connected between the front gear box (not shown) and the hub **218**. Shock absorbers **224** with springs are coupled between the chassis, specifically brackets on the front bars **110**, and the upper arms **212**. Loads are transferred through the front bars **110** to the dash bar **124**, the roll cage **20**, and the front frame members **122** and so forth to bridge to the rear of the vehicle **10**.

[0090] Turning to the rear suspension, FIGS. 7A through 7C are illustrative. Somewhat similar to the front suspension **32**, rear suspension **38** is preferably constructed with a four-bar linkage arrangement. Each side of the suspension includes an upper arm **226**, a lower A-arm **228**, and a rear knuckle **232**. The upper and lower arms **226**, **228** are secured to the chassis rear portion **108** through suspension brackets **230** secured between rear support members **142** and rear lower frame members **136**. A rear shock and spring assembly **234** is secured between the lower A-arm **228** and a shock absorber bracket **236** on each side. The shock absorber brackets **236** are secured to the rear support members **142** and rear upper frame members **138**.

[0091] The rear sway bar assembly interacts with the rear suspension **38**. A sway bar **238** links the right and left lower A-arms **228**. Sway bar **238** extends rearward of the rear tubes **140** and is mounted to the rear tubes **140** with sway bar mounts **240** secured to a rear bracket **241** that extends between rear tubes **140**. Sway bar mounts **240** hold sway bar **238** from translational movement while allowing rotational movement. After extending beyond rear tubes **140**, the sway bar **238** bends forward to the outboard sides of the suspension brackets **230** and inboard of the shock absorber and spring assemblies **234**. The forward ends of sway bar **238** are coupled to sway bar links **242** that extend downwardly to couplings with lower A-arms **228**. Lower A-arms **228** include

cross members **229** extending from forward to rearward portions of lower A-arms **228**. The lower ends of links **242** are secured to the cross members **229**. See FIGS. 7B and 7C.

[0092] As shown in FIGS. 8A-D, the engine **26**, transaxle **84**, and CVT **86** are also positioned within chassis rear portion **108**. The engine **26** is positioned forwardly of the transaxle **84**. The CVT **86** is driven by the engine **26** and drives the transaxle **84**, preferably on the left side of the engine and transaxle. As discussed above, engine front mounts **146** are fastened to the front of the engine crankcase. Engine front mounts **146** are “L” shaped to fasten to the crankcase at various locations and provide a lower mounting location to the chassis rear portion **108**. A frame bracket **244** is held above rear lower frame members **136**. The frame bracket **244** secures isolation members **246** on the top thereof. Isolation members **246** are preferably typical engine mounts that include metal fasteners isolated with rubber to allow vibrational movements of the engine without translating all such engine vibrations to the chassis.

[0093] The rearward end of the transaxle **84** is secured to the rearward end of the chassis rear portion **108**. As mentioned above, mount brackets **148** are secured to the rearward case of the transaxle **84**. Frame brackets **248** are secured to the rear tubes **140** and the suspension bracket **230**. Frame brackets **248** provide a mount for rear isolation members **250** that are placed between frame bracket **248** and mount bracket **148**. Rear isolation members **250** are similar to isolation members **246**. As will be discussed in more detail below, the engine **26** and transaxle are coupled together. Thus, with two isolation members used at the rear of transaxle **84** and two used at the front of engine **26**, the engine-transaxle assembly is secured to the chassis **12** with four isolation members for a secure arrangement that isolates vibrations from the transmitting to the chassis and vehicle occupants. As the CVT is also coupled to the engine and transaxle, and not directly to the frame members, it too is isolated from the chassis with the isolation members **246**, **250**. Other components, including the engine air intake tract also benefit from this isolation mounting, as will be described below.

[0094] The engine **26** and transaxle **84** are coupled with an engine plate **252** and a transaxle plate **254** that are fastened together. A single coupling plate or simply fasteners from the engine to the transaxle are employed in alternate embodiments. The engine plate **252** is fastened to the engine crankcase and includes a portion facing the transaxle plate **254**, which is fastened to the transaxle **84**. The two plates are secured together with fasteners. Providing two plates fastened together provides for the construction of the plates with accurate tolerances for securement to the engine and transaxle mounting locations.

[0095] The transaxle transfers power to the front axles through a forwardly extending transaxle shaft **256** drivingly coupled to a driveshaft **258**. The driveshaft **258** extends under engine **26** and center console **160** toward the front of the vehicle **10**. The driveshaft **258** extends beneath (and between in plan view) the engine front mounts **146** and isolation members **246**. A spline connection **260** couples the transaxle shaft **156** and driveshaft **258** while allowing some small movement between them as the chassis slightly flexes while the vehicle **10** is in operation. A front driveshaft **262** is coupled to driveshaft **258** to extend the driveline to the front gearbox. The driveshaft **258** and front driveshaft **262** are secured together with another spline connection. A frame coupler **264** is preferably placed near the connection to secure the front driveshaft in place while allowing for rotational movement.

[0096] The transaxle transfers power to the rear axle through the transaxle rear drive **267** with splined couplings that open to the right and left of the rear portion of the transaxle **84**. The rear half shafts are secured to the transaxle rear drive **267**.

[0097] FIG. 8B further illustrates the interconnection of the engine **26** and the transaxle **84**. The engine plate **252** is secured to the engine **26** with appropriately situated engine plate mount tabs **265** extending therefrom. The plate is preferably fastened to the engine case. The engine plate is manufactured by being cut then stamped to position the tabs **265** correctly for alignment with the engine mount locations.

[0098] Likewise, the transaxle plate **254** is preferably cut and stamped into shape. Alternatively, it may be forged or cast or made by other methods. Transaxle plate mount tabs **266** are formed to securement to the front of the transaxle case above the transaxle shaft **256**. Six fasteners secure the engine plate **252** to the transaxle plate **254**.

[0099] In placing the engine into the chassis, the engine **26** and transaxle **84** are fastened together first with mount plates **254**, **252**, then the assembly is placed within the chassis rear portion **108**. The engine front mounts **146** and transaxle rear mount **148** are preferably secured to the engine **26** and transaxle **84** prior to inserting the assembly as well. In one embodiment, the CVT secured to the engine and transaxle prior to insertion of the assembly.

[0100] FIG. **8C** again shows the rear chassis portion **108** without the engine **26** and transaxle **84**. A shift cable **268** is shown held by a bracket. This cable extends from the lower end of the shift lever **188**. It is connected to the shift arm **270** of the transaxle **84** (shown in FIG. **8D**).

[0101] FIG. **8D** also illustrates the connection of the CVT **86** to the engine **26** and transaxle **84**. The CVT **86** is connected to an input shaft **272** of the transaxle **84** and to a crankshaft **274** of the engine **26**. The CVT **86** includes a drive clutch **276** driven by the crankshaft **274** and a driven clutch **278** mounted on the input shaft **272**. A belt **280** is coupled between the sheaves of the drive and driven clutches **276**, **278** for achieving continuously variable gear ratios as the crankshaft changes speed. The fixed connection between the engine and transaxle along with the combined isolation mounting of the engine and transaxle to the chassis also aids in the operation of the CVT, as the distance between the axis of rotation of the drive clutch **276** and that of the driven clutch is maintained substantially constant. This helps reduce power losses and increase belt life.

[0102] FIGS. **9A-G** illustrate the air intake tract for the engine as well as the CVT cooling air intake and exhaust. The airbox **88** includes an airbox body **282** that is formed of sufficient shape and volume to be tuned to the engine for optimum performance. Note that the airbox **88** is also close to the engine **26** such that the pulsing air needs of the combustion chambers are met with the large volume of the airbox **88**. The airbox body **282** is closed with an airbox cover **284** secured with clips **286** spaced around the periphery thereof. The cover **284** faces rearwardly to be readily accessible for access to the interior of the airbox **88** for maintenance. An airbox lower mount **288** secures the airbox to the transaxle mount bracket **148**, such that the airbox is isolated with the engine **26** and transaxle **84** to move therewith relative to the chassis **12**.

[0103] FIG. **9A** also shows the CVT cover **290** positioned over the clutches **276**, **278**. Removal of the cover allows access to the clutches and belt **280**.

[0104] FIG. **9B** further illustrates routing of the engine air intake duct **92** to the airbox from the air intake opening **90** to an airbox flex coupling **292** on the forward portion of the airbox body **282**. The flex coupling allows the airbox **88** to move relative to the intake duct **92**, which is mounted to the chassis **12**.

[0105] A CVT exhaust duct **294** is also shown in FIG. **9B**. This duct extends from the rearward end of the CVT **86**, above the driven clutch to an air dump location forward of the CVT **86**.

[0106] FIG. **9C** illustrates the lower mounting arrangement of the airbox **88**. The airbox body **282** includes lower mount tabs **296** extending downwardly from the bottom thereof. The tabs **296** are secured with fasteners to the airbox lower mount **288**. As mentioned above, lower mount **288** is in turn secured to the transaxle rear mount **148** that is attached to the isolation members **250**. Thus, the airbox **88** is not directly fixed to the chassis **12**.

[0107] FIGS. **9D** and **9E** show the preferred arrangement of intake components between the airbox **88** and the engine **26**. A throttle body **300** and an intake manifold **302** are secured in line with the airbox **88** and engine **26** across a short distance. The length of the throttle body **300** and intake manifold **302** essentially define the distance. Thus, the air from the airbox **88** is readily available to the combustion chamber of the engine **26**. A throttle body coupling **304** is over-molded onto a flange on the forward end of the airbox body **282**. This coupling **304** is clamped to the rearward end of the throttle body **300**. Likewise, a manifold coupling **306** is over-molded onto the rearward

end of the intake manifold **302**. The rearward end of the manifold coupling is clamped to the forward end of the throttle body **300**. The couplings **304**, **306** are somewhat elastic, but are of sufficient rigidity to support the components with the assistance of an airbox upper bracket **308**. Bracket **308** extends between the airbox body **282**, the throttle body **300**, and the intake manifold **302**. Note that fuel injectors **310** are operatively connected to the forward ends of intake manifold **302**.

[0108] FIG. **9E** also shows a duct hanger secured to an upper portion of the intake duct **92** to secure the duct to the rear chassis portion **108**. The intake duct **92** is channeled up from the entrance opening to avoid water and debris from proceeding to the airbox **88**. A drain **322** shown in FIG. **9F** also aids in removing any moisture that does enter the airbox **88**. A shield **320** forms a wall between an airbox intake opening **318** and an air filter **312**. Thus any moisture is channeled away from the filter **312** to exit drain **322**.

[0109] A filter mount **314** and a mount fastener **316** secure the air filter in place over a filter frame **326** (seen in FIG. **9G**). FIG. **9F** also shows an airbox gasket **324** received between airbox body **282** and airbox cover **284**. A recess in the edge of cover **284** helps to hold the gasket **324** in place.

[0110] Besides the filter frame **326**, FIG. **9G** also shows the airbox exit flange **328**. The flange **328** is in-line with the throttle body **300** and intake manifold **302**, as discussed above.

[0111] Some aspects of the positioning of radiator **170** were shown and discussed above. FIGS. **10A-C** further clarify the arrangement at the front of the vehicle **10**. As noted above, the radiator **170** is positioned laterally between the right and left headlights **64**. Longitudinally, the radiator **170** is positioned between the bumper bars **114** and the front bars **110**. Vertically, the radiator **170** is positioned between the winch **62** and the tops of the bumper bars **114** about even with the tops of the headlights **64**. An oil cooler **330** is positioned adjacent an upper front face of the radiator **170**. A fan **332** is positioned adjacent the rear face of the radiator **170** to pull air through the radiator when needed for additional cooling.

[0112] Details of a fuel tank **334** will now be described in connection with FIGS. **11A** through **11C**. The fuel tank **334** is positioned beneath and behind the passenger seat **16**. It is nested into the undercarriage frame **118** of the chassis mid portion **106**. The fuel tank **334** includes a fuel duct **336** and a fuel cap **338**. The fuel duct **336** extends upwardly and outwardly from the rear portion of the tank **334** to a terminus at the fuel fill recess **168** of the right-side panel **54**. The cap **338** is securable to the end of the duct **336**. As shown in FIG. **11A**, the fuel tank **334** is held down by seat support frame **132**. Removal of seat support frame **132** is necessary to remove the fuel tank **334**. The rearward end of fuel tank **334** extends upwardly to provide additional volume rearward of the lower portion of the passenger seat **16**. As shown in FIG. **11C**, recesses **339** along the lower edges of the fuel tank **334** allow the tank to nest within the undercarriage frame **118**, including lower rail **120**. Thus, the tank is securely held between undercarriage frame **118** and seat support frame **132**.

[0113] FIG. **11B** illustrates the positioning of a fuel pump **340** in an upper-most portion of the rear of the tank **334**. A fuel coupling **342** is also positioned adjacent the pump **340**.

[0114] The front left corner of fuel tank **334** includes a large recess to receive the vehicle battery. A battery tray **344** is secured to the undercarriage frame **118** to hold the bottom of the battery.

[0115] The positioning of the fuel tank and the battery under the passenger seat **16** of the vehicle **10** somewhat balances the right to left weight of the vehicle, especially if a passenger is not riding along. This positioning also maintains a low center of gravity with these relatively heavy components-fuel and battery-being at the bottom of the vehicle.

[0116] Overall, the center of gravity of the vehicle is kept longitudinally and vertically near the hip or lower spine of the driver. The center of mass of the driver is preferably longitudinally between the center of the wheelbase and the center of mass of the vehicle **10**. Vertically, the preferred clearance of the center of the vehicle is approximately 10 inches above the ground. The seat index point ("SIP") of the driver is approximately 14 inches above the underside of the chassis mid portion **106**. Thus, the occupants feel like they are riding "down in" the vehicle in a low, stable

location. This positioning aids in controlling the vehicle as the occupants are not jostled about as the vehicle **10** is driven over rough terrain. Yet the visibility of the occupants is still adequate. [0117] The present disclosure is also generally directed to a vehicle configured such that the center of gravity of the vehicle is very near the center of gravity of the passenger. In one preferred embodiment, the longitudinal center of gravity of the passenger is between the midpoint between the axles and the center of gravity of the vehicle. In some embodiments, the passenger's center of gravity is assumed to be generally at a certain point relative to the passenger. [0118] For example, the center of gravity can be assumed to be at the passenger's hip, or at a point near the navel as the passenger sits in the vehicle. The center of gravity can be positioned outside of the passenger's physical body. The center of gravity may change depending on the configuration of the seats and the passenger's posture within the vehicle. The vehicle's center of gravity can be at the same vertical, longitudinal, and lateral position as the passenger's center of gravity. For vehicles having side-by-side seating, the center of gravity of the vehicle is generally aligned with the centerline of the vehicle, and accordingly is placed between the driver and passenger seats. In some embodiments, the vehicle's center of gravity is higher than the passenger's center of gravity. In other embodiments, the vehicle's center of gravity is slightly lower than the passenger's center of gravity. Further details of the present disclosure are given in more detail with reference to FIG. **12** below.

[0119] The vehicle's center of gravity (or “center of mass”) can be aligned with the passenger's spine at a low position of the spine, such as near the passenger's tailbone. The forces imparted to the passenger by the vehicle will therefore be perceptibly minimized. In some embodiments, the wheel vehicle's center of gravity is rearward of the midpoint of the wheelbase. For example, the center of the wheelbase can be generally near the longitudinal midpoint of the vehicle (equidistant between the front and rear extremes of the vehicle), and the vehicle center of mass is preferably at a longitudinal position 60% from the effective front axle of the vehicle and 40% from the effective rear axle of the vehicle (i.e. 60/40 weight distribution). The seats can be positioned with the passenger's center of mass somewhere longitudinally between these two points. As the vehicle moves over varied terrain, bumps in the road cause the vehicle to move about these two points as a function of the suspension. In an example, if the vehicle had a perfectly rigid suspension, movement over varied terrain would cause the vehicle to move about the midpoint of the wheelbase. Conversely, if a vehicle with a perfectly elastic suspension traveled over the same varied terrain, the vehicle would move about the center of mass. Since neither of these theoretical extremes can be achieved, the realistic vehicle with some suspension will move about a point somewhere between these two points. Positioning the passenger's center of mass within this envelope causes the perceived motion of the vehicle to be less. Positioning the passenger within this longitudinal envelope provides the smoothest ride to the passenger for a given suspension configuration. The smoothest ride allows the passenger to maintain the best control of the vehicle under speed and uneven terrain. Thus, ideally, if the longitudinal weight distribution of the vehicle places the center of gravity of the vehicle 40% from the effective rear axle, the longitudinal center of gravity of the passenger is placed between 40% and 50% distant from the rear axle.

[0120] FIG. **12** is a schematic illustration of a vehicle **1210** configured according to embodiments of the present disclosure. The vehicle **1210** can be a four-wheeled vehicle having two front vehicle **1212** on a front axle **1212a**, two rear wheels **1213** on a rear axle **1213a**, two seats **1214**: a driver's seat and a passenger's seat. The vehicle **1210** can be an all-terrain vehicle (“ATV”) or a recreational off-highway vehicle (“ROV”), a two-or three-wheeled vehicle, or any other suitable type of wheeled vehicle.

[0121] The vehicle can have any suitable drive train, such as 4×4, 2×4, etc. The vehicle **1210** can be made of a frame and a roll cage **1215** that generally encloses the passenger area and protects the passengers in case of a roll-over or other circumstance. The vehicle **1210** can have a spider frame construction. In some embodiments, the vehicle **1210** has doors (not shown) to the passenger area

that extend downward to the lower portion of the seat **1214** or lower such as below the seat **1214**. The vehicle **1210** preferably includes a radiator **1219** positioned rearward of the seats **1214** and above the engine. The vehicle **1210** can have a suspension system **1221** that can be a trailing-arm suspension, an A-link suspension, or any other suitable type of suspension system **1221**. The vehicle **1210** can include a cargo bed **1222** at a rear position or at another position such as near the front of the vehicle **1210** or laterally outside the passenger area or above the passenger area. The vehicle **1210** can include a fuel tank **1223** which can be positioned rearward of the engine **1216**, above or rearward of the transmission **1218** and engine **1216**, or elsewhere. The vehicle **1210** can also include other common vehicle components, such as a battery, a spare tire, tire changing equipment such as a jack, and other such vehicle components.

[0122] The vehicle **1210** has an engine **1216**, a transmission **1218**, and other standard vehicle equipment positioned variously throughout the vehicle **1210**. The transmission **1218** can be positioned rearward of the engine **1216**, or forward of the engine as shown by **1218'**. In other embodiments, the engine **1216** and transmission **1218** can be at a same lateral or longitudinal position. The transmission **1218** can be a continuously variable transmission (CVT), or another suitable type of transmission. The transmission **1218** can have a drive clutch and a driven clutch. In some embodiments, the drive clutch is forward of the driven clutch; in others, the driven clutch is forward of the drive clutch.

[0123] Any of these vehicle components can be positioned to achieve a desired weight distribution for the vehicle **1210**. The vehicle **1210** therefore has a center of gravity or center of mass ("COM") **1230** at a certain point in the vehicle **1210**. A COM is generally defined as the mean location of all the mass in a system. In certain embodiments, the seats **1214** are positioned within the vehicle **1210** such that the passenger's COM **1220** is superimposed on the COM **1230** of the vehicle **1210** in at least the longitudinal and vertical directions. In some embodiments, the vehicle's COM **1230** and the passenger's COM **1220** are exactly superimposed in one or more of the longitudinal and vertical directions. The vehicle's COM **1230** can also be superimposed with the passenger's COM **1220** in the lateral direction. In other embodiments, there is some distance between the vehicle's COM **1230** and the passenger's COM **1220**. This distance is referred to herein as the center-center distance. In some embodiments, the passenger's COM **1220** is assumed to be near an appropriate portion of the passenger's body, such as the hip area or the navel. In some embodiments, the vehicle **1210** can be configured such that the vehicle's COM **1230** is aligned or nearly aligned with the passenger's spine. Minimizing the distance between the vehicle COM **1230** and the passenger's spine can improve the passenger ride in the vehicle **1210**. Of course, passengers have different body types with different center of mass positions; however, there are several approximations for passenger COM that are used in the industry. For example, a Seat Index Point ("SIP") **1240** is generally used by seatbelt manufacturers to approximate the position of the passenger when seated in the seat **1214**. The SIP can be measured according to SA E Standard No. J 1163 200612, published Dec. 4, 2006. Another point is the ANSI point **1238** that is defined by the ANSI/ROHVA 1-201X standard as approximately 152 mm above the lowest point **1236** of the occupant-supporting surface, and 254 mm forward of the seat back. In other literature, the ANSI point can be defined as being in line with a vertical transverse plane of the vehicle approximately equidistant between the front and rear axle. In some particular embodiments, the vertical transverse plane can be 0.05% closer to one axle than to another. In other words, the ratio between the distance between the vertical transverse plane and an axle (either the front or the rear) and the wheelbase is approximately 49.55%. In several embodiments of the invention, the passenger COM **1220** can be approximated by any one of these reference points alone, or any two or more in combination. For example, the passenger COM **1220** can be approximated by an arithmetic average of the SIP **1240** and the ANSI point **1238**, or any other suitable combination.

[0124] The vehicle **1210** can have an equal weight distribution between the front axle **1212a** and the rear axle **1213a**. In other embodiments, the vehicle weight distribution can be uneven, favoring

the front or rear axles **1212a**, **1213a**. In one particular preferred embodiment, the weight distribution is a 40/60 front/rear distribution, with approximately 40% of the vehicle weight bearing on the front vehicle **1212**, and 60% of the vehicle weight bearing on the rear wheels **1213**. In other words, a distance **D1** between the vehicle COM **1230** and the rear axle **1213a** is approximately 40% of a distance **D4** between the front axle **1212a** and the rear axle **1213a**. [0125] The distance **D1**, between the vehicle COM **1230** and the rear axle **1213a** is approximately 982.9 mm in the longitudinal direction, and the distance **D4** between the front axle **1212a** and the rear axle **1213a** is approximately 2413.6 mm in the longitudinal direction. For purposes of description, a generally horizontal plane **1258** parallel with and running through the front axle **1212a** and the rear axle **1213a** is used for reference. The vehicle COM **1230** can be spaced apart from the plane **1258** by a distance **D6**, which can be approximately 274.4 mm in the vertical direction. In some embodiments, the SIP **1240** can be spaced apart from the rear axle **1213a** by a distance **D2** in the longitudinal direction, and from the plane **1258** by a distance **D7** in the vertical direction. Distances **D2** and **D7** can be 1091.5 mm and 332.3 mm, respectively. In several embodiments, the ANSI point **1238** can be spaced apart from the rear axle **1213a** by a distance **D3** in the longitudinal direction, and from the plane **1258** by a distance **D8** in the vertical direction. Distances **D3** and **D8** can be 1196 mm and 373.9 mm, respectively.

[0126] The position of the engine **1216** and transmission **1218**, and any other vehicle components, can be varied in any suitable manner to achieve the desired relationship between the vehicle COM **1230** and the passenger COM **1220**. The engine **1216** and transmission **1218** can be positioned behind the seat **1214**, and more specifically, with the transmission **1218** positioned behind the engine **1216**. In certain embodiments, the engine **1216** and transmission are at approximately the same vertical level relative to the vehicle **1210**. The vehicle **1210** can include a radiator **1219** which can be positioned above the engine and/or transmission as shown. The radiator **1219** can be angled rearwardly to intake air from above and rearward of the radiator **1219** and direct it toward the engine **1216** and other internal components. The position of the radiator **1219** can be varied to achieve a desired vehicle COM **1230**. To keep the COM biased somewhat rearwardly as desired for off-road vehicles, the radiator is placed behind the longitudinal center of the vehicle. Various other configurations are possible to achieve the desired weight distribution.

[0127] The front axle **1212a** and the rear axle **1213a** can be positioned relative to the vehicle **1210** such that the midpoint between them is spaced apart longitudinally from the vehicle COM **1230** by a certain distance. For example, assuming **D3** is the distance between the rear axle **1213a** and the midpoint of the wheelbase and **D1** is the distance between the rear axle **1213a** and the vehicle COM **1230**, the distance **D2** defines a longitudinal envelope between these two points. In other embodiments the midpoint of the wheelbase can be rearward of the vehicle COM **1230**. In preferred embodiments, the passenger's COM **1220** is positioned somewhere between these two points **D1** and **D3**. As the vehicle moves over varied terrain, bumps in the road cause the vehicle **1210** to move about these two points as a function of the suspension. In an example, if the vehicle **1210** had a perfectly rigid suspension, movement over varied terrain would cause the vehicle **1210** to tend to move about the midpoint of the wheelbase. Conversely, if a vehicle with a perfectly elastic suspension traveled over the same varied terrain, the vehicle **1210** would tend to move about the center of mass. Since neither of these theoretical extremes can be achieved, the realistic vehicle with some suspension will effectively move about a point somewhere between these two points. Positioning the passenger's center of mass within this envelope causes the perceived motion of the vehicle to be less and therefore passenger comfort is improved.

[0128] FIG. **13** is a schematic illustration of a vehicle and seat configuration according to embodiments of the present disclosure that shows the effects of a small or large center-center distance on the ride of the vehicle **1210**. The center-center distance can have a lateral component, a vertical component, and a longitudinal component. When the vehicle's COM **1230** and the passenger's COM **1220** are at the exact same position, the center-center distance is zero. The larger

the center-center distance is, the more an uneven terrain impacts the passenger's ride. For example, if the center-center distance has a large vertical component (because the vehicle's COM is higher or lower than the passenger's COM-the typical case) or a large longitudinal component (because the vehicle's COM is farther forward or back than the passenger's COM), movement of the vehicle about the lateral axis (pitch) moves the passenger as a function of center-center distance. FIG. 13 shows a first seat **1242** with a COM **1220** aligned with a vehicle's COM **1230**. In this example, at least the vertical and longitudinal components of the center-center distance are zero. As the seat **1242** rocks back and forth about the lateral axis, or pitch axis, such as when the vehicle **1210** goes over a bump, the passenger in the seat **1242** moves between a first position **1242a** and a second position **1242b**. The movement of the passenger in the seat **1242** is minimal. The second seat **1242** is shown with an exaggerated vertical center-center distance. With the same vehicle movement, the passenger in the second seat **1242** moves a great deal more between a first position **1242a** and a second position **1242b**. The perceived movement of the passenger is approximately linearly related to the center-center distance about any given axis. If the center-center distance has a large longitudinal or lateral component, the passenger will feel the movement more when the vehicle **1210** rotates about the vertical axis, or yaw axis; if the center-center distance has a large lateral or vertical component, the passenger will feel the movement more when the vehicle rotates about the longitudinal axis. The vehicle configuration of the present disclosure minimizes the center-center distance and thereby improves the ride of the vehicle **1210**. Thus, positioning the passenger vertically close to the COM and between D1 and D3 of the vehicle improves the ride quality perceived by the passenger.

[0129] It should be noted that when the passenger sits in the vehicle the suspension is becomes slightly more compressed, thus lowering the vehicle slightly and, depending on the suspension arms, widening the vehicle track. Because of this configuration, the stability of the vehicle improves when there are passengers seated in the vehicle **1210**.

[0130] In some embodiments, the center-center distance in the longitudinal and vertical direction is zero or nearly zero. In other words, the vehicle's COM **1230** is at the same longitudinal position and vertical position as the passenger's COM **1220**. The vehicle's COM **1230** can be at a lateral midpoint of the vehicle **1210**, and the seats **1214** can be equally spaced from the midline of the vehicle. Assuming two side-by-side passengers have equal weight, in this configuration the vehicle's COM **1230** and the passenger's collective COM **1220** are at the same point longitudinally, vertically, and laterally. In some embodiments, the vehicle **1210** can have a single, center-mounted seat in which case the driver's COM **1220** can be exactly or nearly exactly superimposed upon the vehicle's COM **1230**. In many other configurations, however, there is some center-center distance in at least one dimension. In some embodiments, the passenger's COM **1220** is less than approximately **100** cm from the vehicle's COM **1230** in the longitudinal or vertical direction. In other embodiments, the center-center distance can be greater, such as between **100-400**. In some embodiments the passenger's COM **1220** is above or below the vehicle's COM **1230** or in front of or behind the vehicle's COM **1230** or any workable combination thereof (e.g. above and behind, below and in front of, etc.). As previously noted the passenger COM is preferably slightly forward of the vehicle COM **1230** in a vehicle with a heavier weight distribution on the rear axle.

[0131] In some embodiments, the seats **1214** of the vehicle **1210** are constructed and positioned so that the passenger's COM **1220** is closer vertically to the vehicle's COM **1230** than conventional ROVs or other vehicles. Conventional side-by-side off-road recreational vehicles have seats that are positioned so that the passenger's COM is over 20 cm higher than the vehicle's COM, causing the passenger to undesirably move forward and backward as the vehicle rocks about a lateral axis.

[0132] In contrast to some conventional vehicles, the center-center distance of the present disclosure can be small even though the bottom of the seat **1214** is spaced apart from the bottom of the vehicle **1210** by a distance D9. Some vehicles, such as some sandrails, are configured with the

bottom of the seat very near to the bottom (or floor) of the vehicle. Conventional recreational off-road vehicles have a seating area more than 10 cm (typically 12.5 cm) higher than D9 above the bottom of the vehicle chassis.

[0133] While the preferred embodiments of the invention have been illustrated and described, as noted above, many changes can be made without departing from the spirit and scope of the invention. For example, a second row of seats can be provided. Accordingly, the scope of the invention is not limited by the disclosure of the preferred embodiment. Instead, the invention should be determined entirely by reference to the claims that follow.

Claims

1. A side-by-side recreational off-highway vehicle having two front wheels and at least two rear wheels, the vehicle comprising: a chassis having a front portion, a middle portion, and a rear portion; the front portion being coupled to the front wheels, the rear portion being coupled to the rear wheels, and the middle portion surrounding an occupant compartment having at least two side-by-side seats for a driver and at least one passenger; an engine including a cylinder head, wherein the cylinder head is positioned in the rear portion of the chassis; a transmission secured to the engine; a drive unit operably coupled to the transmission, the drive unit drivingly coupled to the rear wheels; a cover between the engine and the occupant compartment to separate the engine from the occupant compartment; and an access panel secured within the cover, the access panel being movable to access an engine component.
2. The side-by-side recreational off-highway vehicle of claim 1, wherein the chassis includes an engine mount positioned rearward of the passenger compartment.
3. The side-by-side vehicle of claim 2, wherein an isolation member is provided on the engine mount.
4. The side-by-side vehicle of claim 3, wherein the cylinder head is rearwardly tilted, the cylinder head being positioned at least partially rearward of the driver seat.
5. The side-by-side vehicle of claim 4, wherein the access panel is located centrally on the vehicle between the seats of the driver and the passenger.
6. The side-by-side vehicle of claim 5, wherein the access panel includes one or more securement tabs extending therefrom, the one or more tabs being engageable with the cover.
7. The side-by-side vehicle of claim 6, wherein the engine component includes an oil dipstick.
8. The side-by-side vehicle of claim 7, wherein the engine component includes an oil filter.
9. The side-by-side vehicle of claim 6, wherein the panel includes a tab engageable by hand to remove the access panel from the surrounding cover.
10. The side-by-side vehicle of claim 9, wherein the tab is located centrally from side to side on the vehicle between the seats of the driver and the passenger.
11. The side-by-side vehicle of claim 10, wherein the tab is located on an upwardly facing surface of the access panel.
12. The side-by-side vehicle of claim 11, further comprising a battery cover within the vehicle cabin, wherein the battery cover is positioned along the width of the vehicle between a door and the access panel.
13. The side-by-side vehicle of claim 12, wherein a cargo bed is positioned above at least a portion of the cylinder head of the engine.
14. The side-by-side vehicle of claim 13, wherein the engine mount is positioned rearward of the passenger compartment.
15. The side-by-side of claim 1, wherein a fuel tank is positioned at least partially beneath the passenger seat.

16. The side-by-side of claim 1, wherein the drive unit includes a continuously variable transmission.
