BASKETBALL TOY

Abstract

A basketball toy includes a ball, a doll being in a shape of a human, a goal model including a ring, and a launching device being configured to launch the doll diagonally upward. first and second arm parts include first and second hands respectively. A torso has first and second holes, and an arm operation mechanism. The arm operation mechanism is configured inside the torso to operate the first and second arm parts relative to the torso. The arm operation mechanism is configured to hold the first arm part at the first movement position, and hold the second arm part at the third movement position. The arm operation mechanism is configured to render the first and second hands to be close enough to hold the ball when the first and second arm parts are at the first movement position and the third movement positions respectively.

Background/Summary

CROSS-REFERENCE TO THE RELATED APPLICATION

[0001] The present application claims priority under 35 U.S.C. 119 to Japanese Patent Application No. 2024-019197 filed on Feb. 13, 2024. The entire content of Japanese Patent Application No. 2024-019197 is incorporated herein by reference.

BACKGROUND

Technical Field

[0002] The present invention relates to a basketball toy.

Background Art

[0003] Conventionally, as a basketball toy includes a doll resembling a player, a ring disposed above the doll, a slider that vertically moves support members supporting the doll, and a jumping action generating means that moves the slider upward by pressing an operation part (Patent Document 1).

[0004] According to this basketball toy, when the player presses the operating part, the slider moves upward. If the pressing force on the operating part is appropriate, the doll is configured to put the ball into the ring.

[0005] Patent Document 1: Japanese Patent Application Publication No. 7-194838

SUMMARY

Problems the Invention is Intended to Solve

[0006] However, in this basketball toy, the problem was that the doll there only moves upward by operating the operating part, but the basketball toy lacked dynamism as a basketball toy capable of shooting. The present invention has been made in view of such circumstances, and aims to provide a basketball toy capable of performing dynamic shots.

Means for Solving the Problem

[0007] A basketball toy includes a ball, a doll being in a shape of a human, a goal model including a ring, and a launching device being configured to launch the doll diagonally upward. The doll includes a head, a torso, and first and second arm parts extending upward to above the head to hold the ball above the head. The first and second arm parts include first and second hands respectively. The torso has first and second holes, and an arm operation mechanism. The first and second arm parts include first and second shafts respectively. The first shaft is inserted in the first hole to be rotatable relative to the torso between a first movement position and a second movement position around the first shaft part as a center. The second shaft is inserted in the second hole to be rotatable relative to the torso between a third movement position and a fourth movement position around the second shaft part as a center. The arm operation mechanism is configured inside the torso to operate the first and second arm parts relative to the torso. The arm operation mechanism is configured to hold the first arm part at the first movement position, and hold the second arm part at the third movement position. The arm operation mechanism is configured to render the first and second hands to be close enough to hold the ball when the first and second arm parts are at the first movement position and the third movement positions respectively. The arm operation mechanism is configured to allow the first and second arm parts to rotate to the second movement position and the fourth movement position respectively due to the inertia force applied on the ball when the torso hits the ring, and configured to release the ball by separating the first and second arm parts

come apart when the first and second arm parts are at the first and second movement positions respectively.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] FIG. 1 is a perspective view of the basketball toy.

[0009] FIG. 2 is a perspective view of the ball.

[0010] FIG. 3(A) is a perspective view from the side of the doll in the first rotational position, and FIG. 3(B) is a perspective view from the side of the doll in the second rotational position.

[0011] FIG. 4 is an exploded perspective view of the doll seen from the back.

[0012] FIG. 5 is a back view showing the arms and connecting members.

[0013] FIG. 6(A) is a side perspective view from the back showing the connecting member and its surroundings in the first rotational position, and FIG. 6(B) is a side perspective view from the back showing the connecting member and its surroundings in the second rotational position.

[0014] FIG. 7 is a perspective view from the front showing the connecting member and its surroundings in the first rotational position.

[0015] FIG. 8 is a perspective view from the back of the launching device.

[0016] FIG. 9 is a perspective view of the striker plate.

[0017] FIG. 10 is a side sectional view showing the doll set in the launching device.

[0018] FIG. 11 is a perspective view of the goal model seen from the side.

[0019] FIG. 12 is a perspective view of the ball stand.

[0020] FIG. 13 is a diagram showing the flight of the doll in the first example of play.

[0021] FIG. 14 is a side view showing the shooting scene of the doll in the first example.

[0022] FIG. 15 is a side view showing the shooting scene of the doll in the first example.

[0023] FIG. 16 is a diagram showing the flight of the doll in the second example of play.

[0024] FIG. 17 is a diagram showing the flight of the doll in the third example of play.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

[0025] Below, the basketball toy according to an embodiment of the present invention will be described with reference to the drawings.

[0026] FIG. 1 is a perspective view of the basketball toy **100**.

[0027] The basketball toy **100** includes a ball **10**, a doll **20** resembling a player, a launching device **40**, a goal model **50**, and a ball stand **60**.

[0028] An overview of playing with this basketball toy **100** is as follows. First, place the ball **10** in the arms **24L** and **24R** (extended up to a head **21** of the doll **20** as shown in FIG. 3A). Next, set the doll **20** onto the launching device **40**. When the player operates an operating part **41a**, the doll **20** is launched into the air towards the goal model **50**. The doll **20** hits a ring **54**. Upon impact, the doll **20** swings its arms **24L** and **24R** towards a backboard **53** (FIG. 11). Then, the doll **20** releases the ball **10**, which falls into the ring **54**. Meanwhile, after releasing the ball **10**, the doll **20** falls due to its weight. Depending on how well the doll **20** hits the ring **54**, the arms **24L** and **24R** may attach to the ring **54**, causing the doll **20** to hang from the ring **54**.

[0029] Next, this basketball toy **100** will be explained in detail.

Ball **10**

[0030] FIG. 2 is a perspective view of the ball **10**.

[0031] The ball **10** is generally made of plastic. However, it may also be formed from rubber or other materials.

[0032] On the outer circumference of the ball **10**, there is one fitting hole **11a** corresponding to each of the arms **24L** and **24R** of the doll **20**. Each fitting hole **11a** is drilled from the outer circumference of the ball **10** towards the center of the ball **10**. These fitting holes **11a** are designed

to be fitted with fitting protrusions **26aL** and **26aR** of the doll **20**, as described later.

[0033] Additionally, attachment parts **12**, which form one part of a hook-and-loop fastener, are attached to the outer circumference of the ball **10**. These attachment parts **12** are capable of attaching to attachment parts **27** of the doll **20**, which is also described later.

Doll **20**

[0034] FIGS. **3** (A), (B) show perspective views of the doll **20** from the side. FIG. **4** is an exploded perspective view of the doll **20** viewed from the back, and FIG. **5** is a back view showing the arms **24L**, **24R** and the connecting member.

[0035] The doll **20** is generally made of plastic.

[0036] The doll **20** is made of a doll body **20A** including the head **21**, a torso **22**, and movable left and right leg parts **23L**, **23R**, and movable left and right arm parts **24L**, **24R** attached to the doll body **20A**.

[0037] The doll body **20A** is made of a front shell **25a** and a rear shell **25b**, which are interconnected by screws (not shown).

[0038] The arms **24L** and **24R** are shaped in a “<” shape, where hand parts **26L**, **26R** and forearms bend backwards relative to the upper arms. This configuration makes it easier for the doll **20** to perform a dunk shot.

[0039] Additionally, the arms **24L** and **24R** extend up to the head **21** to allowing the hand parts **26L**, **26R** to hold the ball **10** above the head **21**.

[0040] The hand parts **26L** and **26R** are each shaped like an elliptical cylinder, with one end of the major axis of each ellipse connected to the corresponding forearm. One of the two end faces (flat surfaces) of each ellipse forms the palm of the doll **20**. The palms of the hand parts **26L** and **26R** face each other.

[0041] Each palm has the fitting protrusions **26aL**, **26aR** that can fit into the fitting holes **11a**, **11a** of the ball **10**. These fitting protrusions **26aL**, **26aR** are semi-spherical, but they could also be cylindrical. The key is that the fitting protrusions **26aL**, **26aR** and the fitting holes **11a**, **11a** of the ball **10** have complementary shapes, allowing for fitting and release.

[0042] Furthermore, the attachment parts **27**, which form part of a hook-and-loop fastener, are attached to the outer peripheral surface of each hand part **26L**, **26R**, corresponding to the fingertip and side areas.

[0043] The axel parts **28L**, **28R** forming the base of the arms **24L**, **24R** are loosely fitted into axle holes **29L**, **29R** formed on the shoulders of the doll **20** by the front shell **25a** and the rear shell **25b**. The edges of the axle holes **29L**, **29R** serve as pivot support points during the rotation of the arms **24L**, **24R**.

[0044] The axel parts **28L** and **28R** extend to the center of the width of the torso **22**. Extension parts **30L** and **30R** are mutually connected at the center of the width of the torso **22** by a shaft **31**. The assembly formed by these extension parts **30L**, **30R**, and a shaft **31** enables the arms **24L**, **24R** to pivot integrally around the axel parts **28L**, **28R**.

[0045] Between the extension part **30R** and the internal fixed part of the torso **22** (not shown), a coil spring **32** is attached. The coil spring **32** pulls the extension part **30R** downward. The coil spring **32** biases towards bringing the hand parts **26L**, **26R** closer to each other and moving the arms **24L**, **24R** towards the first movement position. At the first joint of the arms **24L**, **24R**, a hemispherical protrusion (holding part) **33a** is provided on the shaft **31** or the shaft parts, and when in the first movement position, as shown in FIG. **6**(A), the protrusion **33a** is in contact with an internal fixed part **33b** of the torso **22** and pushes the protrusion **33a** downward to engage with the fixed part **33b**. The “first movement position” refers to the position of the arms **24L**, **24R** shown in FIG. **3**(A).

[0046] In this first movement position, the arms **24L**, **24R** are held in place by the biasing force of the coil spring **32** with the protrusion **33a** in contact with the fixed part **33b**. Also, due to a certain inertia force, as shown in FIG. **6**(B), the arms **24L**, **24R** move to the second movement position

where the contact between the protrusion **33a** and the fixed part **33b** is released. The “second movement position” refers to the position of the arms **24L**, **24R** shown in FIG. **3(B)**.

[0047] In the second movement position, the shaft **31** is positioned at the same height as the axel parts **28L**, **28R**. In other words, in the second movement position, the shaft **31** is positioned on a straight line connecting the axel parts **28L**, **28R**. In the embodiment of the doll **20**, when the shaft **31** is in this position, the distance between the hand parts **26L**, **26R** is maximized. Also, in the first movement position, the shaft **31** is pressed downward by the internal fixed part **33B** of the torso **22**, and the position where the protrusion **33a** and the distance between the hand parts **26L**, **26R** are minimized is maintained by the coil spring **32**.

[0048] When the arms **24L**, **24R** are in the first movement position, the distance between the hand parts **26L**, **26R** is small, making it difficult to hold the ball **10** in the hand parts **26L**, **26R**. Therefore, when holding the ball **10**, the arms **24L**, **24R** are rotated to the second movement position to hold the ball **10**, and then the arms **24L**, **24R** are returned to the first movement position.

[0049] FIG. **7** is a perspective view from the front showing the connector in the first operational position and its surroundings. As shown in the figure, one end of the coil spring **32** is attached to the front side of the extension part **30R**. The coil spring **32** biases the arms **24L**, **24R** towards each other and towards the first operational position, rotating them. By moving (rotating) the arms **24L**, **24R** to the first operational position due to this coil spring **32**, the projection **33a** presses downward against the fixed part **33b** of the torso **22**, maintaining the position set so that the distance between the arms **24L**, **24R** and the hand parts **26L**, **26R** is minimized.

[0050] Additionally, protrusions **32L**, **32R** extending downward are provided on the extension parts **30L**, **30R**. These protrusions **32L**, **32R** are spaced apart in the first operational position. On the other hand, on the inner surface of the torso **22**, there is a sliding contact section **33** where the protrusions **32L**, **32R** slide when the arms **24L**, **24R** rotate from the first operational position to the second operational position. The sliding contact section **33** induces relative displacement of the extension parts **30L**, **30R** centered on the axis **31** due to the sliding contact between the protrusions **32L**, **32R** and the sliding contact section **33**. The sliding contact of the protrusions **32L**, **32R** with the sliding contact section **33** of the coil spring **32** occurs just after the projection **33a** moves away from the fixed part **33b** inside the torso **22**, and as the arms **24L**, **24R** begin to rotate from the first operational position to the second operational position, the protrusions **32L**, **32R** rotate towards the front shell **25a** and slide into the sliding contact section **33**. Due to this sliding contact between the protrusions **32L**, **32R** and the sliding contact section **33**, the distance between the hand parts **26L**, **26R** gradually increases. Therefore, when holding the ball **10** with the hand parts **26L**, **26R**, the fitting protrusion **26aL**, **26aR** are released from the fitting holes **11a**, **11a** of the ball **10** at the second operational position. When the arms **24L**, **24R** reach the second operational position, the protrusions **32L**, **32R** come into contact, preventing further separation of the hand parts **26L**, **26R**. [0051] The extension parts **30L**, **30R**, the axis **31**, the coil spring **32**, the protrusion **33a**, the fixed part **33b**, and the protrusions **32L**, **32R** constitute the arm movement mechanism.

Launching Device **40**

[0052] FIG. **8** is a perspective view of the launching device **40**. In the following description of the launching device **40**, directions in FIG. **8** are defined as front, back, left, right, and up.

[0053] In this embodiment, the launching device **40** is equipped with a lever mechanism to strike and propel the doll **20**.

[0054] The launching device **40** includes a long striking plate **41**. A striking plate **41** is attached to a housing **42**.

[0055] The housing **42** is elongated in the front-back direction when viewed from above, forming a rectangular shape. The housing **42** is configured with a front wall **42b**, a left wall **42c**, and a right wall **42d** erected on a base plate **42a**. The striking plate **41** is installed within the space surrounded by the front wall **42b**, left wall **42c**, and right wall **42d**.

[0056] FIG. **9** is a perspective view of the striking plate **41**.

[0057] The striking plate **41** is elongated in the front-back direction and is pivotally supported by the left wall **42c** and right wall **42d** at the midpoint along its length.

[0058] The back end of the striking plate **41** serves as the operating part **41a** pressed down by the player. On the other hand, the front end of the striking plate **41** serves as a doll placement part **41b** for placing the doll **20**.

[0059] The doll placement part **41b** is configured in a lower compartment divided by a step **41c** provided on the upper surface of the striking plate **41**. The doll **20** is placed on the doll placement part **41b** with its front facing forward towards the launching device **40**. At this time, the heel of the doll **20** hits the step **41c**, preventing the doll **20** from shifting position. This configuration is illustrated in the side sectional view of FIG. **10**.

[0060] In the center of the doll placement part **41b** in the left-right direction, a partition wall **41d** extending in the front-back direction is formed. The left and right areas separated by the partition wall **41d** constitute individual places for placing the left and right legs **23L**, **23R** of the doll **20**. On the upper surface of each place, fishcake-shaped protrusions **41eL**, **41eR** extend left and right. The protrusions **41eL**, **41eR** come into contact with the arch-like part of each foot of the doll **20** when the doll **20** is placed on the doll placement part **41b**. These protrusions **41eL**, **41eR** always exert force on the arch-like part of the doll **20**'s foot, regardless of the angle of the striking plate **41** for launching the doll **20**.

[0061] Furthermore, on the inner surface of the front wall **42b** of the housing **42**, when the doll **20** is placed on the doll placement part **41b**, the doll **20** leans against it. This causes the doll **20** to be launched diagonally upward and forward from the front of the housing **42**.

[0062] Additionally, at the back of the housing **42**, a striking plate angle limiting member **42e** is provided to pivotally restrain the movable angle of the striking plate **41**. During firing, by raising the striking plate angle limiting member **42e** and placing the operating part **41a** against the striking plate angle limiting member **42e**, it becomes possible to adjust the amount of forward rotation or twist when the doll **20** is launched at close range.

Goal Model **50**

[0063] FIG. **11** is a perspective view of the goal model **50** seen from the side.

[0064] The goal model **50** includes the backboard **53** provided on a pillar **52** of a stand **51**, and the ring **54** is attached to the backboard **53**. Attached to the upper outer periphery of the ring **54** is an attachment part **55** that forms one side of a hook-and-loop fastener.

Ball Stand **60**

[0065] FIG. **12** is a perspective view of the ball stand **60**.

[0066] The ball stand **60** includes a ball placement part **62** on top of a pillar **61**. The pillar **61** can be made extendable and retractable by using an accordion-style, screw-style, telescopic-style, or ratchet-style extension mechanism.

Gameplay

When Not Using Ball Stand **60**

a. Long-Distance Launch

[0067] Attach the ball **10** to the left and right arms **24L**, **24R** extending from the head **21** of the doll **20**. Next, set the doll **20** on the launching device **40**. Then, the player forcefully strikes the operating part **41a** of the striking plate **41** to launch the doll **20**.

[0068] In this case, if successful, as shown in FIG. **13**, the launched doll **20** rotates once in mid-air with half a twist. In other words, the doll **20** hits the ring **54** with its back towards it, as shown in FIG. **14**. The impact stops the doll body at the ring **54**, but the ball **10** and arms **24L**, **24R** move towards the backboard **53** due to inertia, as shown in FIG. **15**. As a result, the arms **24L**, **24R** rotate from the first rotational position to the second, and the hand parts **26L**, **26R** holding the ball **10** reach the top of the ring **54**. Here, the ball **10** is released and drops into the ring **54**.

[0069] On the other hand, after releasing the ball **10**, the doll **20** falls due to its own weight. If it

falls well, during the descent, the attachment parts 27 of the hand parts 26L, 26R of the doll 20 attach to the attachment parts 55 of the ring 54, causing the doll 20 to hang from the ring 54.

b. Short-Distance Launch

[0070] Attach the ball 10 to the left and right arms 24L, 24R extending from the head 21 of the doll 20. Next, set the doll 20 on the launching device 40. Then, the player lightly strikes the operating part 41a of the striking plate 41 to launch the doll 20.

[0071] In this case, for example, as shown in FIG. 16, when the doll 20 rotates half a turn in mid-air, it enters the ring 54 headfirst from the head 21. If successful, the ball 10 or the arms 24L, 24R hit the ring 54, and due to the inertia acting on the doll body 20A, the arms 24L, 24R rotate to the second rotational position, releasing the ball 10. Afterward, the doll 20 may either fall down, or it may rotate half a turn backwards on the ring 54, with the attachment parts 27 of the hand parts 26L, 26R attaching to the attachment parts 55 of the ring 54, hanging the doll 20 from the ring 54. It's also possible for the doll 20 to remain inside the ring 54.

When Using Ball Stand 60

[0072] When using ball stand 60, do not attach the ball 10 to the arms 24L, 24R of the doll 20. Set the doll 20 on the launching device 40 in this state. Ensure that the attachment parts 12 of the ball 10 faces towards the launching device 40 during setup. Then, the player forcefully strikes the operating part 41a of the striking plate 41 to launch the doll 20.

[0073] During flight, as shown in FIG. 17, one attachment part 27 of the hand parts 26L, 26R of the doll 20 hits the attachment parts 12 of the ball 10, causing the ball 10 to adhere to one of the hand parts 26L, 26R of the doll 20. In this state, the doll 20 rotates at least once, and only its hand reaches into the ring 54. This causes the attachment parts 12 to detach from the attachment part 27, releasing the ball 10.

[0074] Additionally, the doll 20 continues to fall.

[0075] Thus, the manner in which the doll 20 flies and reaches the ring 54 can vary depending on factors such as the intensity of operation of the operating part 41a, and the positioning of the doll 20. By adjusting the position of the launching device 40, the intensity of operation of the operating part 41a, and the positioning of the doll 20, various changes can be made to enjoy a game with variability.

[0076] Above, the gameplay of the basketball toy 100 in the embodiment has been described. It goes without saying that the behavior of the doll 20 can vary depending on factors such as the distance between the launching device 40 and the goal model 50, the orientation of the launching device 40, and the strength of operation of the striking plate 41.

Effects of the Embodiment

[0077] According to the basketball toy 100 of the embodiment, the following effects can be achieved:

[0078] Specifically, with the basketball toy 100, the doll 20 can fly through the air using the launching device 40 and score the ball 10 into the ring 54, thus enabling a dynamic dunk shot.

[0079] Furthermore, each of the arms 24L, 24R is bent in a "<" shape towards the direction of rotation from the first to the second action position relative to the upper arm, making it easier for the hand parts 26L, 26R holding the ball 10 to operate on the ring 54.

[0080] Moreover, the hand parts 26L, 26R have a thickened structure, with attachment parts 27 attached to the tip and side surfaces. The attachment parts 55 are attached to the outer periphery of the ring 54, allowing the doll 20 to hang on the ring 54 after shooting.

[0081] Additionally, the launching device 40 is equipped with a long striking plate 41 supported by the housing 42 at the midpoint in the longitudinal direction. The operating part 41a is provided at one end of the longitudinal direction of the striking plate 41, and a doll placement part 41b for placing the doll 20 is provided at the other end. This allows the doll 20 to be easily launched into the air using the lever principle.

[0082] Furthermore, the striking plate 41 is formed with the step 41c so that the doll placement part

41b becomes a lower section, and the protrusions **41eL**, **41eR** are formed to extend along the short direction of the striking plate **41** to contact the arch of the doll **20**. The arrangement allows the striking force to act on the arch part of the doll **20** regardless of the angle of the striking plate **41** at the time of launch.

[0083] Furthermore, the housing **42** is equipped with a front wall **42b** provided in the forward direction of the launch, a left wall **42c** provided to the left in the launch direction, and a right wall **42d** provided to the right in the launch direction. The striking plate **41** is provided within the area surrounded by the front wall **42b**, left wall **42c**, and right wall **42d**, and is configured so that the doll **20** placed there leans against the front wall **42b**, making it easier to propel the doll **20** forward and upward diagonally.

Variants

[0084] Thus far, embodiments of the present invention have been described, but the present invention is not limited to such embodiments and various modifications are possible.

[0085] For example, in the embodiments, a launching device **40** is used to propel the doll **20** using the lever principle, but it is also possible to propel the doll **20** using the spring biasing force.

[0086] Additionally, in the embodiments, an example was shown where the doll **20** performs a backward dunk shot, but the invention can also be applied when the doll **20** performs a forward dunk shot.

[0087] For instance, by reversing the configuration of the arms **24L**, **24R** and the arm operating mechanism to operate the doll **20** in a backward direction, the front part of the doll **20** can be positioned against the ring for performing a forward dunk shot.

[0088] Moreover, by launching the doll **20** in a backward direction, it is possible to configure the doll **20** to perform a forward dunk shot by positioning the front part of the doll **20** against the ring. It is well known that when launching a doll into the air, the rotational behavior of the doll varies depending on factors such as the center of gravity of the doll holding the ball, the striking position, the balance of the strike from left to right, and the magnitude of the striking force.

[0089] Therefore, by reversing the configuration of the arms **24L**, **24R** and the arm operating mechanism and adjusting the center of gravity position of the doll holding the ball, it is possible to launch the doll **20** in a forward direction and enable a forward dunk shot.

[0090] In another embodiment, the arms **24L** and **24R** are moved from the first movement position to the second movement position by inertia force. At the first movement position, the arms **24L** and **24R** are engaged by a locking member against the urging force of a spring, and upon collision of the doll **20** with the ring **54**, a locking release member is pressed, releasing the engagement of the arms **24L** and **24R** by the locking member, allowing the arms **24L** and **24R** to move to the second movement position due to the urging force of the spring.

[0091] Furthermore, in the above embodiment, the urging force of the coil spring **32** is configured to allow the protrusion **33a** on the lower side of the fixed part **33b** inside the torso **22** to slide in, but it may also be configured for manual sliding only at the sliding point.

[0092] Also, in the above embodiment, the protrusion **33a** is pressed downward by the fixed part **33b** inside the torso **22**, minimizing the distance between the hand parts **26L** and **26R**. However, it may alternatively be configured simply to hold the minimized distance between the hand parts **26L** and **26R** by the contact between the fixed part **33b** inside the torso **22** and the protrusion **33a**, where the minimizing is achieved by the urging force of the coil spring **32**.

[0093] According to the embodiments, the basketball toy can perform dynamic shots by launching the doll into the air with the launching device and putting the ball into the ring.

Claims

1. A basketball toy comprising: a ball, a doll being in a shape of a human, a goal model including a ring, and a launching device being configured to launch the doll diagonally upward, the doll

including a head, a torso, and first and second arm parts extending upward to above the head to hold the ball above the head, the first and second arm parts including first and second hands respectively, the torso has first and second holes, and an arm operation mechanism, the first and second arm parts include first and second shafts respectively, the first shaft is inserted in the first hole to be rotatable relative to the torso between a first movement position and a second movement position around the first shaft part as a center, the second shaft is inserted in the second hole to be rotatable relative to the torso between a third movement position and a fourth movement position around the second shaft part as a center, the arm operation mechanism is configured inside the torso to operate the first and second arm parts relative to the torso, the arm operation mechanism is configured to hold the first arm part at the first movement position, and hold the second arm part at the third movement position, the arm operation mechanism is configured to render the first and second hands to be close enough to hold the ball when the first and second arm parts are at the first movement position and the third movement positions respectively, the arm operation mechanism is configured to allow the first and second arm parts to rotate to the second movement position and the fourth movement position respectively due to the inertia force applied on the ball when the torso hits the ring, and configured to release the ball by separating the first and second arm parts come apart when the first and second arm parts are at the first and second movement positions respectively.

2. The basketball toy according to claim 1 comprises: an interconnected body including first and second extension parts extending from the first and second arm parts inside the torso, a third shaft connecting the first and second extension parts at a center of the torso in a width direction thereof, the interconnected body being integrally rotatable with the first and second arm parts around the third shaft and being configured to separate the first and second hands by the first and second extension parts relatively moving around a center of the third shaft, the torso including a fixed part, and a folding joint part, the interconnected body further including a spring urging the first and second hands closer to each other and urging both the first and second arm parts towards the first movement position, a holding part engaging with the fixed part at the first movement position to maintain both the first and second hands close to each other, and a sliding contact section being configured to slide against the folding joint part when the first and second arm parts rotate to the second movement position in order to relatively move the first and second extension parts around the center of the third shaft.

3. The basketball toy according to claim 1, wherein the first and second arm parts include first and second forearms respectively, the first forearm and the first hand form a “<” shape extending in a direction from the first movement position to the second movement position, and the second forearm and the second hand form a “<” shape extending in a direction from the first movement position to the second movement position.

4. The basketball toy according to claim 1, wherein the ball includes, on an outer surface thereof, first and second fitting holes, where the first fitting hole is configured opposite to the second fitting hole across a center of the ball, the first and second hands include first and second surfaces respectively and first and second fitting projections respectively, the first and second surface are flat and configured to contact the ball, and the first and second fitting projections are inserted into the first and second fitting holes respectively when the ball is held by the first and second hands.

5. The basketball toy according to claim 4, wherein the goal includes a first attachment part being configured on an outer peripheral surface of the ring, and a second attachment part, and a third attachment part, the first hand has an elliptical cylinder shape, the second hand has the elliptical cylinder shape, a first end of the elliptical cylinder shape of the first hand in a longitudinal direction is connected to the first forearm part, a second end of the elliptical cylinder shape of the second hand in a longitudinal direction is connected to the second forearm part, the second attachment part is configured on the first surface of the first hand, the third attachment part is configured on the second surface of the second hand, the second and the third attachment parts are attachable to the

first attachment part.

6. The basketball toy according to claim 1, further comprising a housing, wherein the launching device includes a long striking plate, and is configured to launch the doll using a principle of leverage the long striking plate includes an intermediate portion in a longitudinal direction, and operating section, the operating section is configured at one end of the longitudinal direction of the striking plate, and the doll placement section is configured at the other end of the longitudinal direction of the striking plate.

7. The basketball toy according to claim 6, wherein the launching device includes a step on an upper surface of the striking plate, the step dividing the doll placement section to an upper part and a lower part, the doll placement section is formed in the lower part of the step, the doll includes a foot including an arch, the striking plate includes a protrusion that corresponds to the arch, and the protrusion is elongated in a short direction of the striking plate.

8. The basketball toy according to claim 7, wherein the housing includes a front wall being configured in front of the launching direction of the doll, a left wall provided to left of the launching direction, and a right wall provided to right of the launching direction, the striking plate is configured in a space surrounded by the front wall, the left wall, and the right wall, and the doll placement section is configured so that the doll leans against the front wall.
