ABSTRACT

Liquid chromatography systems and liquid chromatography components are disclosed. In an embodiment, a liquid chromatography system includes a liquid chromatography component. The liquid chromatography component includes a substrate and an amorphous coating on the substrate. The amorphous coating has a base layer and a surface layer. The base layer includes carboxysilane.

FIG. 2

LIQUID CHROMATOGRAPHY SYSTEM AND COMPONENT

PRIORITY

[0001] The present application is a non-provisional continuation patent application claiming priority and benefit of U.S. provisional patent application No. 62/212,868, filed on Sep. 1, 2015, directed to “BATCH THERMAL CVD SILICON PARTICULATE REDUCTION AND/OR ELIMINATION,” PCT Patent Application PCT/US2016/049647, filed on Aug. 31, 2016, directed to “THERMAL CHEMICAL VAPOR DEPOSITION COATING,” and U.S. non-provisional patent application Ser. No. 15/755,962, filed on Feb. 27, 2018, directed to “THERMAL CHEMICAL VAPOR DEPOSITION COATING,” now U.S. Pat. No. 10,876,206, U.S. non-provisional patent application Ser. No. 16/870,034, filed on May 8, 2020, directed to “LIQUID CHROMATOGRAPHY SYSTEM AND COMPONENT,” now U.S. Pat. No. 11,131,020, U.S. non-provisional patent application Ser. No. 17/411,545, filed on Aug. 25, 2021, directed to “LIQUID CHROMATOGRAPHY SYSTEM AND COMPONENT,” now U.S. Pat. No. 12,037,685, and U.S. non-provisional patent application Ser. No. 18/743,370, filed on Jun. 14, 2024, directed to “LIQUID CHROMATOGRAPHY SYSTEM AND COMPONENT,” now U.S. Pat. No. 12,291,778, all of which are incorporated by reference in their entirety.

FIELD OF THE INVENTION

[0002] The present invention is directed to liquid chromatography systems and liquid chromatography components. More particularly, the present invention is directed to such systems/components having an amorphous coating.

BACKGROUND OF THE INVENTION

[0003] Silicon has been applied to various surfaces through thermal chemical vapor deposition. Silicon has been applied through static processes involving pump and purge cycling of a reaction vessel, with periods of a gaseous soak within the reaction vessel. Alternatively, silicon has been applied in flow-through systems that involve constant flow of a gas through a reaction chamber, which do not include the gaseous soak and include features that do not allow conditions for flow-through systems to translate to conditions for systems that are not flow-through.

[0004] The silicon applied by static processes and by flow-through processes provide various improvements in various applications. Such applications have included flow-paths, fittings, fixtures, connectors, and other components. Flow-through processes allow for a constant or substantially constant concentration of a precursor gas to contact a surface, which is desirable because it allows for coatings to be applied with no gas phase nucleation. However, such flow-through processes are limited to line-of-sight techniques that coat surfaces within a direct line or substantially close to the direct line. Such flow-through processes are expensive and wasteful by having an over-abundance of the gas precursor that does not deposit on such surfaces.

[0005] Atomic layer deposition allows coating of regions that are not line-of-sight or close to a direct line. However, atomic layer deposition is a single layer process that has substantial economic challenges due to the prolonged processing conditions required to achieve coating.

[0006] Prior techniques of using thermal chemical vapor deposition have addressed above drawbacks of flow-through techniques and atomic layer deposition. However, many of the prior techniques produce gas phase nucleation based upon particle-particle collisions during the reaction process. The gas phase nucleation forms a dust, for example, a silicon dust when silane is thermally reacted.

[0007] U.S. Pat. No. 6,511,760, which is incorporated by reference in its entirety, teaches processes and vessels that allow thermal chemical vapor deposition that is substantially free of silicon dust. Such levels are of a concentration below that in which silicon dust can settle on a surface, compromise the integrity of the silicon layer formed on a metal surface, and/or create a physical barrier between successive layers of silicon.

[0008] Certain industries are extremely sensitive. They require reproducibility that has previously been considered to be beyond the functional possibility for thermal chemical vapor deposition and were only capable of being satisfied through wasteful flow-through techniques. For example, certain industries have needs relating to silicon dust concentration are beyond that which those in the thermal chemical vapor deposition industry would consider to be substantially free of dust. Although the amount of dust may be at levels below in which silicon dust can settle on the surface, compromise the integrity of the silicon layer formed on the metal surface, and/or create a physical barrier between successive layers of silicon, such levels can be too high for certain industries.

[0009] Coated articles and thermal chemical vapor deposition processes that shows one or more improvements in comparison to the prior art would be desirable in the art.

BRIEF DESCRIPTION OF THE INVENTION

[0010] In an embodiment, a liquid chromatography system includes a liquid chromatography component. The liquid chromatography component includes a substrate and an amorphous coating on the substrate. The amorphous coating has a base layer and a surface layer. The base layer includes carboxysilane.

[0011] Other features and advantages of the present invention will be apparent from the following more detailed description, taken in conjunction with the accompanying drawing which illustrates, by way of example, the principles of the invention.

BRIEF DESCRIPTION OF THE DRAWING

[0012] FIG. 1 is a schematic perspective view of a thermal chemical vapor deposition coating process, according to an embodiment of the disclosure.

[0013] FIG. 2 is a micrograph of an exemplary coating, according to an embodiment of the disclosure.

[0014] Wherever possible, the same reference numbers will be used throughout the drawing to represent the same parts.

DETAILED DESCRIPTION OF THE INVENTION

[0015] Provided are coated articles and thermal chemical vapor deposition processes. Embodiments of the present disclosure, for example, in comparison to concepts failing to include one or more of the features disclosed herein, increase consistency/repeatability of coating, improve aes-

thetics, modify microstructure, modify optical properties, modify porosity, modify corrosion resistance, modify gloss, modify surface features, permit more efficient production of coatings, permit coating of a wide range of geometries (for example, narrow channels/tubes, three-dimensionally complex geometries, and/or hidden or non-line-of-site geometries, such as, in needles, tubes, probes, fixtures, complex planar and/or non-planar geometry articles, simple non-planar and/or planar geometry articles, and combinations thereof), reduce or eliminate defects/microporosity, permit coating of a bulk of articles, are capable or being used in or replacing components that are used in industries traditionally believed to be too sensitive for processes that are not flow-through processes (for example, based upon compositional purity, presents of contaminants, thickness uniformity, and/or amount of gas phase nucleation embedded within), or permit a combination thereof.

[0016] Referring to FIG. 1, a thermal chemical vapor deposition (“CVD”) process **100** produces a coated article **101**, for example, having features and properties unique to being produced through the thermal CVD process, according to the disclosure, which is a static process using an enclosed chamber or enclosed vessel **113** (for example, within the enclosed chamber) contrasted to flowable chemical vapor deposition that has concurrent flow of a precursor into and out of a chamber. As used herein, the phrase “thermal CVD” or “thermal chemical vapor deposition” refers to a reaction and/or decomposition of one or more gases, for example, in a starved reactor configuration, and is distinguishable from plasma-assisted CVD, radical-initiated CVD, and/or catalyst-assisted CVD, sputtering, atomic layer deposition (which is limited to a monolayer molecular deposition per cycle in contrast being capable of more than one layer of molecular deposition), and/or epitaxial growth (for example, growth at greater than 700° C.).

[0017] The coated article **101** is produced from an uncoated article **111** and includes a substrate **103** (for example, not a silicon wafer) and one or more layers, such as, a base layer **105** in contact with the substrate **103**, one or more interlayers **107** in contact with the base layer **105**, and a surface layer **109** in contact with the interlayer **107** (or the outermost of the plurality of the interlayers **107**). The base layer **105**, the interlayer(s) **107**, and the surface layer **109** define a coating **121**. The coating **121** is on the coated article **101** on regions that are unable to be concurrently coated through line-of-sight techniques. In a further embodiment, the coating **121** is on regions that are unable to be coated concurrently or sequentially through line-of-sight techniques.

[0018] In one embodiment, the process **100** includes positioning one or a plurality of uncoated article(s) **111** within the enclosed vessel **113** (step **102**). In further embodiments, the positioning (step **102**) is manually with the articles **111** being arranged in a vertical (stacked) orientation separated by supports (and thus obstructed from line-of-sight), arranged laterally or perpendicular to gravity (for example, with all or most openings being perpendicular to gravity), arranged in an overlapping manner that reduces the amount of volume available for gas phase nucleation, of a combination thereof.

[0019] After the positioning (step **102**), the process **100** includes introducing a silicon-containing precursor gas to the enclosed vessel **113** (step **104**), for example, as a first aliquot, then gaseously soaking the uncoated article(s) **111**

(step **106**) at a temperature above the thermal decomposition temperature of the silicon-containing precursor gas to produce the base layer **105** of the coated article **101**. The process **100** further includes repeating the introducing of the silicon-containing precursor gas (step **104**), for example, as a second aliquot, or introducing a different silicon-containing precursor gas, to produce the interlayer(s) **107** and the surface layer **109**. The gaseously soaking (step **106**) is at a temperature above the thermal decomposition temperature of the silicon-containing precursor or the different silicon-containing precursors. The process **100** produces the coating **121**.

[0020] The coating **121** has a concentration of particulate from gas phase nucleation (particle to particle collisions) that is below a desired level. Referring to FIG. 2, in one embodiment, the concentration per 100 square micrometers is fewer than 6 particles having a dimension of greater than 0.5 micrometers. Further embodiments have a concentration, per 100 square micrometers, of between 2 and 4 of the particles having a dimension of greater than 2 micrometers, fewer than 3 of the particles having a dimension of greater than 2 micrometers, fewer than 3 of the particles having a dimension of greater than 2 micrometers and fewer than 4 of the particles having a dimension of greater than 1.5 micrometers, or any suitable combination, sub-combination, range, or sub-range therein. In a further embodiment, the coating **121** has no particles of silicon dust formed from gas phase nucleation that are greater than 3 micrometers.

[0021] The concentration of the particulate from the gas phase nucleation (referred to as silicon dust) is controlled by balancing competing factors of the process **100**. Such mechanisms include adsorption, nucleation, transport, surface diffusion, re-adsorption, and desorption. In general, two competing concepts during the process **100** occur: gas phase nucleation and deposition. Gas phase nucleation or particle-to-particle collisions occur at a greater rate when molecules have a greater distance to travel before contacting the substrate **103**.

[0022] The average distance that molecules travel is referred to as the mean free path. The mean free path for a cylinder may be represented by either of the following:

$$\frac{1}{\pi d^2 n_V} \quad (\text{Equation 1})$$

where n_V is the number of molecules per unit volume and d is the diameter of the gas molecules. Other geometries are much more complicated.

[0023] In one embodiment, the process includes having a mean free path that is substantially larger than the distance to the substrate **103**, thereby reducing or substantially eliminating the gas phase nucleation. The mean free path is longer due to selection of higher temperatures and lower pressures, as is capable of being derived by incorporation of the Ideal Gas Law.

[0024] In another embodiment, the mean free path is increased by selecting gas precursors with a smaller molecular diameter. Additionally or alternatively, the mean free path is increased by combining with inert gases, combining with other gas precursors having a smaller molecular diameter, or combining with reactive gases having a smaller diameter.

[0025] Balancing such factors to achieve the desired level of dust is performed by analyzing the impact of parameters of the process 100 in view of differential time capable of being represented with differential equations applied to equations with identified constants. For example, the below equation applies to steady-state conditions where flux to surface equals reaction flux:

$$\begin{aligned} J_1 &= h_G(C_g - C_s) & (\text{Equation 2}) \\ J_2 &= k_s C_s \\ v &= \frac{C_g}{\frac{1}{h_G} + \frac{1}{k_s}} \end{aligned}$$

where J_1 is flux to surface, J_2 is reaction flux, C_g is gas concentration, C_s is concentration on the surface, h_g is gas phase mass transport coefficient, and k_s is surface reaction rate, the surfaces being the substrate 103, the base layer 105, or the interlayer 107.

[0026] In the process 100, the concentration of the precursor gas within the enclosed vessel 113 decreases over time based upon the reactivity of the selected gas and the temperature within the enclosed vessel 113. As such, the rate of deposition decreases over time. At a certain point, nucleation is as likely or more likely than deposition according to the process 100, which results in dust.

[0027] In further embodiments of the process 100, the gas phase nucleation and the deposition are balanced by monitoring parameters selected from the group consisting of time between collisions of molecules of gas and the reactant, cycle time (for example, based upon energy being pumped into the gas phase that pushes gas phase nucleation), gas concentration, surface area per unit volume of vessels or fixtures or other structural features, or a combination thereof.

[0028] The silicon-containing precursor gas(es) is/are any suitable species capable of producing the coating 121 through thermal decomposition. Gases may be gaseous or liquid at ambient temperature, so long as they thermally decompose within the process 100. Suitable gases include, but are not limited to, silane, silane and ethylene, silane and an oxidizer, dimethylsilane, trimethylsilane, dialkylsilyl dihydride, alkylsilyl trihydride, non-pyrophoric species (for example, dialkylsilyl dihydride and/or alkylsilyl trihydride), thermally reacted material (for example, carbosilane and/or carboxysilane, such as, amorphous carbosilane and/or amorphous carboxysilane), species capable of a recombination of carbosilyl (disilyl or trisilyl fragments), methyltrimethoxysilane, methyltriethoxysilane, dimethyldimethoxysilane, dimethyldiethoxysilane, trimethylmethoxysilane, trimethyl-ethoxysilane, one or more nitrogen-containing species (for example, ammonia, nitrogen, hydrazine, trisilylamine (also known as, TSA; silanamine; N,N-disilyl-disilazane; 2-silyl-silane, nitrilotris; or 3SA), Bis (tertiary-butylamino) silane, 1,2-bis(dimethylamino) tetramethyldisilane, and/or dichlorosilane, hexachlorodisilane), and combinations thereof. In embodiments with more than one species being introduced, the species are introduced concurrently (pre-mixed or mixed in situ) or sequentially (with either species being introduced first).

[0029] In general, the gases used in the process 100 are each part of gaseous mixtures including thermally reactive

gas(es) and an inert gas. Suitable concentrations of the thermally-reactive gas(es), by volume, are between 10% and 20%, between 10% and 15%, between 12% and 14%, between 10% and 100%, between 30% and 70%, between 50% and 80%, between 70% and 100%, between 80% and 90%, between 84% and 86%, or any suitable combination, sub-combination, range, or sub-range therein.

[0030] The term “uncoated”, as is used in describing the uncoated article 111, refers to not having the complete deposition of the coated article 101 encompassed by the process 100. For example, embodiments of the process 100 include the uncoated article 111 having an untreated substrate material, a treated substrate material, a cleaned substrate material, a treatment, a binder, an oxidation, any other suitable surface effect, or a combination thereof.

[0031] The coating 121 has any suitable thickness providing the desired properties for the desired application. Suitable thicknesses include, but are not limited to, between 100 nanometers and 10,000 nanometers, between 100 nanometers and 1,000 nanometers, between 100 nanometers and 800 nanometers, between 200 nanometers and 600 nanometers, between 200 nanometers and 10,000 nanometers, between 500 nanometers and 3,000 nanometers, between 500 nanometers and 2,000 nanometers, between 500 nanometers and 1,000 nanometers, between 1,000 nanometers and 2,000 nanometers, between 1,000 nanometers and 1,500 nanometers, between 1,500 nanometers and 2,000 nanometers, 800 nanometers, 1,200 nanometers, 1,600 nanometers, 1,900 nanometers, or any suitable combination, sub-combination, range, or sub-range therein. In further embodiments, thicknesses of the amorphous silicon layer 105 and/or the amorphous interlayer are individually between 100 nm and 5,000 nm, between 200 nanometers and 2,000 nanometers, between 200 nanometers and 1,000 nanometers, between 200 nanometers and 800 nanometers, between 200 nanometers and 1,500 nanometers, between 1,500 nanometers and 2,000 nanometers, 800 nanometers, 1,200 nanometers, 1,600 nanometers, 1,900 nanometers, or any suitable combination, sub-combination, range, or sub-range therein.

[0032] The process 100 is achieved at suitable temperatures and pressures to produce the coated article 101. In one embodiment, after the positioning of the uncoated article(s) 111 within the enclosed vessel 113 (step 102), the temperature within the enclosed vessel 113 is increased from a temperature below the decomposition temperature of the silicon-containing deposition gas 117 to a temperature above the decomposition temperature of the silicon-containing deposition gas 117 prior to, during, and/or after the introducing of the silicon-containing deposition gas 117 (step 104). The introducing of the silicon-containing deposition gas 117 (step 104) is in a single cycle or multiple cycles, for example with intermediate purges. In embodiments with multiple cycles, the introducing of the silicon-containing deposition gas 117 (step 104) is in two cycles, three cycles, four cycles, five cycles, six cycles, seven cycles, eight cycles, nine cycles, ten cycles, eleven cycles, twelve cycles, thirteen cycles, fourteen cycles, fifteen cycles, sixteen cycles, or any suitable combination, sub-combination, range, or sub-range therein.

[0033] In one embodiment, the temperature is greater than 200° C., greater than 300° C., greater than 350° C., greater than 370° C., greater than 380° C., greater than 390° C., greater than 400° C., greater than 410° C., greater than 420° C., greater than 430° C., greater than 440° C., greater than

450° C., greater than 500° C., between 300° C. and 450° C., between 350° C. and 450° C., between 380° C. and 450° C., between 300° C. and 500° C., between 400° C. and 500° C., or any suitable combination, sub-combination, range, or sub-range therein.

[0034] In one embodiment, the partial pressures for the gas(es) is/are between 1 Torr and 10 Torr, 1 Torr and 5 Torr, 1 Torr and 3 Torr, 2 Torr and 3 Torr, 10 Torr and 150 Torr, between 10 Torr and 30 Torr, between 20 Torr and 40 Torr, between 30 Torr and 50 Torr, between 60 Torr and 80 Torr, between 50 Torr and 100 Torr, between 50 Torr and 150 Torr, between 100 Torr and 150 Torr, less than 150 Torr, less than 100 Torr, less than 50 Torr, less than 30 Torr, or any suitable combination, sub-combination, range, or sub-range therein.

[0035] In one embodiment, the one or more gases are held at the temperature and the pressure for a period facilitating desired coverage. Suitable durations include, but are not limited to, at least 10 minutes, at least 20 minutes, at least 30 minutes, at least 45 minutes, at least 1 hour, at least 2 hours, at least 3 hours, at least 4 hours, at least 5 hours, at least 7 hours, between 10 minutes and 1 hour, between 20 minutes and 45 minutes, between 4 and 10 hours, between 6 and 8 hours, or any suitable combination, sub-combination, range, or sub-range therein.

[0036] Purging with an inert gas is capable of being performed to the enclosed vessel **113** during the process **100**. For example, prior to or after the introducing of the silicon-containing deposition gas **117** (step **104**) an inert gas is capable of being introduced to the enclosed vessel **113**. Suitable inert gases include, but are not limited to, nitrogen, helium, and/or argon.

[0037] Oxidizing with an oxidant is capable of being performed to the enclosed vessel **113** during the process **100**. For example, prior to or after the introducing of the silicon-containing deposition gas **117** (step **104**) an oxidant is capable of being introduced to the enclosed vessel **113**. Suitable oxidants include, but are not limited to, water (alone, with zero air, or with an inert gas), oxygen (for example, at a concentration, by weight, of at least 50%), air (for example, alone, not alone, and/or as zero air), nitrous oxide, ozone, peroxide, or a combination thereof. As used herein, the term “zero air” refers to atmospheric air having less than 0.1 ppm total hydrocarbons. The term “air” generally refers to a gaseous fluid, by weight, of mostly nitrogen, with the oxygen being the second highest concentration species within. For example, in one embodiment, the nitrogen is present at a concentration, by weight, of at least 70% (for example, between 75% and 76%) and oxygen is present at a concentration, by weight, of at least 20% (for example, between 23% and 24%).

[0038] The surface layer **109** is capable of being post-cleaned, for example, in a turbulent manner. Additionally or alternatively, cleaning techniques include water deionized flushing with sonication, polyethylene pellets are used to soak up dust (in one application, with a second confirming that no additional dust is produced), CO₂ spray, and/or use of a chemical with good wetting/hydrophilicity (for example, isopropanol, ammonium hydroxide+water+).

[0039] The enclosed vessel(s) **113** has any dimensions or geometry that allows the coated article **101** to be produced within the temperature and the pressures. In one embodiment, the dimensions for the enclosed vessel(s) **113** include, but are not limited to, having a minimum width of greater than 5 cm, greater than 10 cm, greater than 20 cm, greater

than 30 cm, greater than 100 cm, greater than 300 cm, greater than 1,000 cm, between 10 cm and 100 cm, between 100 cm and 300 cm, between 100 cm and 1,000 cm, between 300 cm and 1,000 cm, any other minimum width capable of uniform or substantially uniform heating, or any suitable combination, sub-combination, range, or sub-range therein. Suitable volumes for the enclosed vessel(s) **113** include, but are not limited to, at least 1,000 cm³, greater than 3,000 cm³, greater than 5,000 cm³, greater than 10,000 cm³, greater than 20,000 cm³, between 3,000 cm³ and 5,000 cm³, between 5,000 cm³ and 10,000 cm³, between 5,000 cm³ and 20,000 cm³, between 10,000 cm³ and 20,000 cm³, any other volumes capable of uniform or substantially uniform heating, or any suitable combination, sub-combination, range, or sub-range therein.

[0040] Suitable components capable of being produced into the coated article **101** include, but are not limited to, fittings (for example, unions, connectors, adaptors, other connections between two or more pieces of tubing, for example, capable of making a leak-free or substantially leak-free seal), compression fittings (including ferrules, such as, a front and back ferrule), tubing (for example, coiled tubing, tubing sections such as used to connect a sampling apparatus, pre-bent tubing, straight tubing, loose wound tubing, tightly bound tubing, and/or flexible tubing, whether consisting of the interior being coated or including the interior and the exterior being coated), valves (such as, gas sampling, liquid sampling, transfer, shut-off, or check valves, for example, including a rupture disc, stem, poppet, rotor, multi-position configuration, able to handle vacuum or pressure, a handle or stem for a knob, ball-stem features, ball valve features, check valve features, springs, multiple bodies, seals, needle valve features, packing washers, and/or stems), quick-connects, sample cylinders, regulators and/or flow-controllers (for example, including o-rings, seals, and/or diaphragms), injection ports (for example, for gas chromatographs), in-line filters (for example, having springs, sintered metal filters, mesh screens, and/or weldments), glass liners, gas chromatograph components, liquid chromatography components, components associated with vacuum systems and chambers, components associated with analytical systems, sample probes, control probes, downhole sampling containers, drilled and/or machined block components, manifolds, particles, powders, or a combination thereof.

[0041] In one embodiment, the uncoated article **111**, and thus, the coated article **101** has a non-planar geometry. Exemplary non-planar geometries include having features selected from the group consisting of channels, curves, threading, vanes, protrusions, cavities, junctions, mating interfaces, and combinations thereof. In a further embodiment, all exposed surfaces of the coated article **101** include the base layer **105**, the interlayer(s) **107**, and the surface layer **109**. As used herein, the term “exposed,” with regard to “exposed surfaces,” refers to any surface that is in contact with gas during the process, and is not limited to line-of-site surfaces or surfaces proximal to line-of-site directions as are seen in flow-through chemical vapor deposition processes that do not have the enclosed vessel **113**. As will be appreciated by those skilled in the art, the coated article **101** is capable of being incorporated into a larger component or system (not shown), whether the larger component or the system includes other coated article **101** or not.

[0042] The substrate **103** is any suitable material(s) compatible with the process **100**. Suitable metal or metallic

materials include, but are not limited to, ferrous-based alloys, non-ferrous-based alloys, nickel-based alloys, stainless steels (martensitic or austenitic), aluminum alloys, composite metals, or combinations thereof. Suitable non-metal or non-metallic materials include, but are not limited to, ceramics, glass, ceramic matrix composites, or a combination thereof. Suitable materials may be tempered or non-tempered; may have grain structures that are equiaxed, directionally-solidified, and/or single crystal; may have amorphous or crystalline structures; may be foil, fibrous, polymeric, film and/or coated; or may have any suitable combination or sub-combination thereof that is capable of withstanding the operational temperatures of the process 100.

[0043] In one embodiment, the substrate 103 is or includes a composition, by weight, of up to 0.08% carbon, between 18% and 20% chromium, up to 2% manganese, between 8% and 10.5% nickel, up to 0.045% phosphorus, up to 0.03% sulfur, up to 1% silicon, and a balance of iron (for example, between 66% and 74% iron).

[0044] In one embodiment, the substrate 103 is or includes a composition, by weight, of up to 0.08% carbon, up to 2% manganese, up to 0.045% phosphorus, up to 0.03% sulfur, up to 0.75% silicon, between 16% and 18% chromium, between 10% and 14% nickel, between 2% and 3% molybdenum, up to 0.1% nitrogen, and a balance of iron.

[0045] In one embodiment, the substrate 103 is or includes a composition, by weight, of up to 0.03% carbon, up to 2% manganese, up to 0.045% phosphorus, up to 0.03% sulfur, up to 0.75% silicon, between 16% and 18% chromium, between 10% and 14% nickel, between 2% and 3% molybdenum, up to 0.1% nitrogen, and a balance of iron.

[0046] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 14% and 17% chromium, between 6% and 10% iron, between 0.5% and 1.5% manganese, between 0.1% and 1% copper, between 0.1% and 1% silicon, between 0.01% and 0.2% carbon, between 0.001% and 0.2% sulfur, and a balance nickel (for example, 72%).

[0047] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 20% and 24% chromium, between 1% and 5% iron, between 8% and 10% molybdenum, between 10% and 15% cobalt, between 0.1% and 1% manganese, between 0.1% and 1% copper, between 0.8% and 1.5% aluminum, between 0.1% and 1% titanium, between 0.1% and 1% silicon, between 0.01% and 0.2% carbon, between 0.001% and 0.2% sulfur, between 0.001% and 0.2% phosphorus, between 0.001% and 0.2% boron, and a balance nickel (for example, between 44.2% and 56%).

[0048] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 20% and 23% chromium, between 4% and 6% iron, between 8% and 10% molybdenum, between 3% and 4.5% niobium, between 0.5% and 1.5% cobalt, between 0.1% and 1% manganese, between 0.1% and 1% aluminum, between 0.1% and 1% titanium, between 0.1% and 1% silicon, between 0.01% and 0.5% carbon, between 0.001% and 0.02% sulfur, between 0.001% and 0.02% phosphorus, and a balance nickel (for example, 58%).

[0049] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 25% and 35% chromium, between 8% and 10% iron, between 0.2% and 0.5% manganese, between 0.005% and 0.02% copper, between 0.01% and 0.03% aluminum, between 0.3% and 0.4%

silicon, between 0.005% and 0.03% carbon, between 0.001% and 0.005% sulfur, and a balance nickel (for example, 59.5%).

[0050] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 17% and 21%, between 2.8% and 3.3%, between 4.75% and 5.5% niobium, between 0.5% and 1.5% cobalt, between 0.1% and 0.5% manganese, between 0.2% and 0.8% copper, between 0.65% and 1.15% aluminum, between 0.2% and 0.4% titanium, between 0.3% and 0.4% silicon, between 0.01% and 1% carbon, between 0.001 and 0.02% sulfur, between 0.001 and 0.02% phosphorus, between 0.001 and 0.02% boron, and a balance nickel (for example, between 50% and 55%).

[0051] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 2% and 3% cobalt, between 15% and 17% chromium, between 5% and 17% molybdenum, between 3% and 5% tungsten, between 4% and 6% iron, between 0.5% and 1% silicon, between 0.5% and 1.5% manganese, between 0.005 and 0.02% carbon, between 0.3% and 0.4% vanadium, and a balance nickel.

[0052] In one embodiment, the substrate 103 is or includes a composition, by weight, of up to 0.15% carbon, between 3.5% and 5.5% tungsten, between 4.5% and 7% iron, between 15.5% and 17.5% chromium, between 16% and 18% molybdenum, between 0.2% and 0.4% vanadium, up to 1% manganese, up to 1% sulfur, up to 1% silicon, up to 0.04% phosphorus, up to 0.03% sulfur, and a balance nickel.

[0053] In one embodiment, the substrate 103 is or includes a composition, by weight, of up to 2.5% cobalt, up to 22% chromium, up to 13% molybdenum, up to 3% tungsten, up to 3% iron, up to 0.08% silicon, up to 0.5% manganese, up to 0.01% carbon, up to 0.35% vanadium, and a balance nickel (for example, 56%).

[0054] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 1% and 2% cobalt, between 20% and 22% chromium, between 8% and 10% molybdenum, between 0.1% and 1% tungsten, between 17% and 20% iron, between 0.1% and 1% silicon, between 0.1% and 1% manganese, between 0.05 and 0.2% carbon, and a balance nickel.

[0055] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 0.01% and 0.05% boron, between 0.01% and 0.1% chromium, between 0.003% and 0.35% copper, between 0.005% and 0.03% gallium, between 0.006% and 0.8% iron, between 0.006% and 0.3% magnesium, between 0.02% and 1% silicon+iron, between 0.006% and 0.35% silicon, between 0.002% and 0.2% titanium, between 0.01% and 0.03% vanadium+titanium, between 0.005% and 0.05% vanadium, between 0.006% and 0.1% zinc, and a balance aluminum (for example, greater than 99%).

[0056] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 0.05% and 0.4% chromium, between 0.03% and 0.9% copper, between 0.05% and 1% iron, between 0.05% and 1.5% magnesium, between 0.5% and 1.8% manganese, between 0.5% and 0.1% nickel, between 0.03% and 0.35% titanium, up to 0.5% vanadium, between 0.04% and 1.3% zinc, and a balance aluminum (for example, between 94.3% and 99.8%).

[0057] In one embodiment, the substrate 103 is or includes a composition, by weight, of between 0.0003% and 0.07% beryllium, between 0.02% and 2% bismuth, between 0.01% and 0.25% chromium, between 0.03% and 5% copper, between 0.09% and 5.4% iron, between 0.01% and 2%

magnesium, between 0.03% and 1.5% manganese, between 0.15% and 2.2% nickel, between 0.6% and 21.5% silicon, between 0.005% and 0.2% titanium, between 0.05% and 10.7% zinc, and a balance aluminum (for example, between 70.7% to 98.7%).

[0058] In one embodiment, the substrate **103** is or includes a composition, by weight, of between 0.15% and 1.5% bismuth, between 0.003% and 0.06% boron, between 0.03% and 0.4% chromium, between 0.01% and 1.2% copper, between 0.12% and 0.5% chromium+manganese, between 0.04% and 1% iron, between 0.003% and 2% lead, between 0.2% and 3% magnesium, between 0.02% and 1.4% manganese, between 0.05% and 0.2% nickel, between 0.5% and 0.5% oxygen, between 0.2% and 1.8% silicon, up to 0.05% strontium, between 0.05% and 2% tin, between 0.01% and 0.25% titanium, between 0.05% and 0.3% vanadium, between 0.03% and 2.4% zinc, between 0.05% and 0.2% zirconium, between 0.150 and 0.2% zirconium+titanium, and a balance of aluminum (for example, between 91.7% and 99.6%).

[0059] In one embodiment, the substrate **103** is or includes a composition, by weight, of between 0.4% and 0.8% silicon, up to 0.7% iron, between 0.15% and 0.4% copper, up to 0.15% manganese, between 0.8% and 1.2% magnesium, between 0.04% and 0.35% chromium, up to 0.25% zinc, up to 0.15% titanium, optional incidental impurities (for example, at less than 0.05% each, totaling less than 0.15%), and a balance of aluminum (for example, between 95% and 98.6%).

[0060] In one embodiment, the substrate **103** is or includes a composition, by weight, of between 11% and 13% silicon, up to 0.6% impurities/residuals, and a balance of aluminum.

Examples

[0061] In a first experiment, a stainless steel coupon was coated at 390° C. at a pressure of 7.75 psia for four 30-minute cycles. The coated stainless steel coupon resulted in a coating substantially free of silicon dust, but with dust at a minute concentration of, per 100 square micrometers, greater than 6 particles having a dimension of greater than 0.5 micrometers.

[0062] In a second experiment, a stainless steel coupon was coated at 410° C. at a pressure of 3.87 psia for four 45-minute cycles. The coated stainless steel coupon resulted in a coating substantially free of silicon dust, but with dust at a minute concentration of, per 100 square micrometers, greater than 6 particles having a dimension of greater than 0.5 micrometers.

[0063] In a third experiment, a stainless steel coupon was coated at 410° C. at a pressure of 2.32 psia for four 45-minute cycles. The coated stainless steel coupon resulted in a coating substantially free of silicon dust, but with dust at a minute concentration of, per 100 square micrometers, greater than 6 particles having a dimension of greater than 0.5 micrometers.

[0064] In a fourth experiment, a stainless steel coupon was coated at 410° C. at a pressure of 3.87 psia for four 300-minute cycles. The coated stainless steel coupon resulted in a coating having a substantial amount of silicon dust.

[0065] In a fifth experiment, a stainless steel coupon was coated at 410° C. at a pressure of 2.61 psia for fifteen 30-minute cycles. The coated stainless steel coupon resulted in a coating having a an amount of silicon dust at a concentration of, per 100 square micrometers, less than 6 particles having a dimension of greater than 0.5 micrometers, as shown in FIG. 2.

[0066] While the invention has been described with reference to one or more embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements thereof without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from the essential scope thereof. Therefore, it is intended that the invention not be limited to the particular embodiment disclosed as the best mode contemplated for carrying out this invention, but that the invention will include all embodiments falling within the scope of the appended claims. In addition, all numerical values identified in the detailed description shall be interpreted as though the precise and approximate values are both expressly identified.

What is claimed is:

1. A coated article for a liquid chromatography system comprising:

a substrate; and

an amorphous coating on the substrate;

wherein the amorphous coating includes silicon;

wherein the amorphous coating is devoid of particles of silicon dust formed from gas phase nucleation that are greater than 3 micrometers.

2. The coated article of claim 1, wherein the coated article comprises at least one of the group including a fitting, a compression fitting, a valve, a quick-connect, a sample cylinder, a regulator, a flow-controller, and injection port, an in-line filter, a glass liner, a sample probe, a control probe, a downhole sampling container, a drilled and/or machined block component, and a manifold.

3. The coated article of claim 1, wherein the amorphous coating is positioned on regions of the component that are unable to be concurrently or sequentially coated through line-of-sight techniques.

4. The coated article of claim 1, wherein the amorphous coating has a deposition thickness of greater than 100 nm.

5. The coated article of claim 1, wherein the amorphous coating has a deposition thickness of greater than 1,000 nm.

6. The coated article of claim 1, wherein the amorphous coating is chemically and physically adsorbed to the substrate.

7. The coated article of claim 1, wherein the amorphous coating has homogenous nucleation.

8. The coated article of claim 1, wherein the coated article has a non-planar geometry.

9. The coated article of claim 8, wherein the non-planar geometry is selected from the group consisting of channels, curves, threading, vanes, protrusions, cavities, junctions, mating interfaces, and combinations thereof.
