TECHNICAL FIELD

[0002] The present invention belongs to the field of medicinal chemistry, and in particular relates to a tricyclic compound or pharmaceutically acceptable salt, ester, stereoisomer, tautomer, polymorph, solvate, N-oxide, isotope-labeled compound, metabolite or prodrug thereof, a method for preparing the same, a pharmaceutical composition containing the same, and use thereof.

BACKGROUND ART

[0003] Toll-like receptors (Toll-like receptors, TLRs) belong to the pattern recognition receptor (PRR) family, which can specifically recognize pathogen-associated molecular patterns (PAMP), is an important class of proteins involved in non-specific immunity, and is a bridge between nonspecific and specific immunity. So far, 13 kinds of Toll-like receptors have been found in mammals, and 10 kinds (TLR1-10) have been found in humans, among which TLR1/2/4/5/6/10 are expressed on the cell surface and can quickly recognize the products of bacterial metabolism, TLR3/7/8/9 are expressed in endosomes, which mainly recognize and monitor exogenous nucleic acid substances in pathogen cells.

[0004] TLR7 has a limited expression distribution in humans, and is mainly expressed by B cells and plasmacytoid dendritic cells (pDCs). In response to viral infection, TLR7 induces high levels of interferon- α , and enhances costimulation and antigen presentation ability activation of pDCs, promotes the proliferation of CD4⁺ T cells and further activates CD8⁺ T cells to generate adaptive T cell responses. TLR8 expression is relatively more widespread, and mainly expressed by monocytes, NK cells and myeloid dendritic cells (mDC) in humans. Stimulation of TLR8 can induce the release of various proinflammatory cytokines, such as tumor necrosis factor- α (TNF- α), IL-6, IL-12, and interferon- γ . At the same time, the TLR8 signaling pathway has also been proved to be a necessary and sufficient condition for reversing the suppressive function of Tregs cells. Therefore, TLR7 and TLR8 both play an important role in the body's innate immunity and acquired immunity, and are popular targets for anticancer and antiviral immunotherapy. At present, there have been reports involving multiple TLR7 and/or TLR8 agonists from different companies, but there is still a great demand for TLR7 and/or TLR8 agonists with better activity, safety and physicochemical properties.

[0005] At present, a new type of immune-stimulating antibody conjugate (ISAC) is emerging, which is formed by coupling an immunomodulator such as TLR7 and/or TLR8 agonist with a tumor-targeting antibody through a cleavable/non-cleavable linker. The immune-stimulating

antibody conjugate combines the precise tumor localization of the antibody with the durable anti-tumor activity and immune memory efficacy of the immunomodulator such as TLR7 and/or TLR8 agonist, and safely triggers anti-tumor immune responses while achieving systemic administration. [0006] Therefore, aiming at the above aspects, the present invention provides a class of tricyclic compounds with TLR7 and/or TLR8 agonistic activity. This type of compounds has better activity, safety and physical and chemical properties, and it can be further used in immune-stimulating antibody conjugates, which are of great significance for the development of antitumor and antiviral drugs.

Contents of the Invention

[0007] In one aspect, the present application provides a class of tricyclic compounds, which has strong agonistic effect on TLR7 and/or TLR8, and therefore is better in use for prevention and/or treatment of a disease associated with the mediation of TLR7 and/or TLR8. The compounds also have various excellent properties, such as good physicochemical properties (e.g., solubility, physical and/or chemical stability) and good safety.

[0008] The compound is a compound of Formula (I) or a pharmaceutically acceptable salt, ester, stereoisomer, tautomer, polymorph, solvate, N-oxide, isotope-labeled compound, metabolite or prodrug thereof:

[0074] The compound of the present invention may exist in the form of a solvate, preferably a hydrate, wherein the compound of the present invention comprises a polar solvent as a structural element of the crystal lattice of the compound. The amount of polar solvent, especially water, may be present in stoichiometric or non-stoichiometric ratio.

[0075] Those skilled in the art will appreciate that not all nitrogen-containing heterocycles are capable of forming N-oxides since nitrogen requires available lone pairs of electrons to oxidize to form an oxide. Those skilled in the art will be able to recognize that tertiary amines are capable of forming N-oxides. Synthetic methods for the preparation of N-oxides of heterocycles and tertiary amines are well known to those skilled in the art, and include the use of peroxyacids such as peracetic acid and m-chloroperbenzoic acid (MCPBA), hydrogen peroxide, alkyl hydroperoxides such as t-butyl hydroperoxide, sodium perborate and dioxirane such as dimethyldioxirane to oxidize heterocycles and tertiary amines. These methods for preparing N-oxides have been extensively described and reviewed in the literature, see, for example: T. L. Gilchrist, *Comprehensive Organic Synthesis*, vol. 7, pp 748-750; A. R. Katritzky and A. J. Boulton, Eds., Academic Press; and G. W. H. Cheeseman and E. S. G. Werstiuk, *Advances in Heterocyclic Chemistry*, vol. 22, pp 390-392, A. R. Katritzky and A. J. Boulton, Eds., Academic Press.

[0076] Also included within the scope of the present invention are metabolites of the compounds of the present invention, i.e., the substances formed in vivo upon administration of the compounds of the present invention. Such products may be generated by, for example, oxidation, reduction, hydrolysis, amidation, deamidation, esterification, enzymatic hydrolysis, etc., of the administered compounds. Accordingly, the present invention comprises metabolites of the compounds of the present invention, including compounds produced by contacting the compounds of the present invention with a mammal for a time sufficient to produce metabolites thereof.

[0077] The present invention further comprises within its scope prodrugs of the compounds of the present invention, which are certain derivatives of the compounds of the present invention which themselves may have little or no pharmacological activity and can be converted into the compounds of the present invention with desired activity, for example, by hydrolytic cleavage, when they are administered to or on the body. Typically, such prodrugs are functional group derivatives of the compounds, and are readily converted in vivo into the compounds with the desired therapeutic activity. Additional information on the use of prodrugs can be found in "Prodrugs as Novel Delivery Systems", Vol. 14, ACS Symposium Series (T. Higuchi and V. Stella), and "Bioreversible Carriers in Drug Design," Pergamon Press, 1987 (Edited by E. B. Roche, American Pharmaceutical Association). The prodrugs of the present invention can be obtained, for example, by using certain moieties known to those skilled in the art as "pro-moiety (e.g., as described in "Design of Prodrugs", H. Bundgaard (Elsevier, 1985))" to substitute appropriate functional groups present in the compounds of the present invention.

[0078] The present invention also encompasses the compounds of the present invention which contain protecting groups. During any process for the preparations of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules involved, thereby forming chemically protected forms of the compounds of the present invention. This can be achieved by conventional protecting groups, for example, the protecting groups as described in "Protective Groups in Organic Chemistry", ed. J. F. W. McOmie, Plenum

Press, 1973; and T. W. Greene & P. G. M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991, and all these references are incorporated herein by reference. Protecting groups can be removed at an appropriate subsequent stage using methods known in the art.

[0079] The term “about” means within the range of $\pm 10\%$, preferably within the range of $\pm 5\%$, more preferably within the range of $\pm 2\%$ of the stated value.

[0080] The term “conjugate” refers to a substance obtained by linking a small molecule drug with a targeting moiety. In some embodiments of the present invention, the small molecule drug is linked to the targeting moiety through a linker. The linker can be cleaved under specific environment (e.g., a low intracellular pH environment, an acidic tumor microenvironment) or specific action (e.g., action of lysosomal protease), thereby separating the small molecule drug from the targeting moiety.

[0081] The term “linker” refers to a fragment that links a small molecule drug to a targeting moiety.

[0082] The term “targeting moiety” refers to a portion of a conjugate that is capable of specifically binding to a target (or a portion of target) on the surface of a cell. Through the interaction of the targeting moiety with the target, the conjugate can be delivered to a specific cell population.

[0083] The term “fragment” refers to the remaining part of a compound molecule after losing one or more atoms or atomic groups (e.g., hydrogen atoms or hydroxyl groups). For example “fragment of a compound” refers to the remaining part of a compound obtained by losing a hydrogen atom or a hydroxyl group after the compound described herein is linked to the linker in the immune-stimulating antibody conjugate.

[0084] The term “cross-linking agent” refers to a reagent with the same or different reactive groups at both molecular ends, which can covalently interact with amino groups, sulfhydryl groups, hydroxyl groups or maleimide groups on other molecules to produce crosslinking effect, for example, the cross-linking agent SATA.

[0763] The results showed that the immune-stimulating antibody conjugates ISAC-1, ISAC-2, ISAC-3, ISAC-4, ISAC-5, ISAC-6 and ISAC-7 stimulate more secretion of TNF- α under the co-incubation system of HCC1954 tumor cells and PBMCs in vitro than that of Trastuzumab monoclonal antibody at comparable concentration.

Experimental Example 4: Drug Efficacy Evaluation of ISAC in SCID-Beige Mouse Xenograft Tumor Model

Experimental Steps:

[0764] 1. 5×10^6 HCC1954 cells (mixed with Matrigel at 1:1 in equal volume, suspended in 0.1 mL PBS) were subcutaneously inoculated in the right underarm of each SCID-beige mouse (Weitong Lihua). [0765] 2. When the tumor grew to have an average volume of about 150 mm³, the mice with irregular tumor volume and too small or too large tumor volume were excluded, and the remaining mice were randomly divided into groups according to the tumor volume and animal weight, and administrated with a single intraperitoneal injection (i.p.) of physiological saline (vehicle control), Trastuzumab monoclonal antibody (9.95 mg/kg), immune-stimulating antibody conjugate ISAC-1 (10 mg/kg, same molar concentration as Trastuzumab monoclonal antibody), respectively, and the efficacy of the test compounds on the tumor-bearing mouse model and the animal tolerance of the test compounds were observed. [0766] 3. During the experiment, the mice were weighed twice a week and the tumor volume was measured, and the data were recorded. [0767] 4. Data statistics, tumor volume (V) calculation formula:

$V = 1/2 \times a \times b^2$, wherein a and b represent length and width, respectively. The antineoplastic drug efficacy was evaluated with tumor growth inhibition rate TGI (%), calculation formula: $TGI(\%) = [1 - (T_{sub.Vt} - T_{sub.V0}) / (C_{sub.Vt} - C_{sub.V0})] \times 100\%$, wherein T_{sub.V0} represents the average tumor volume of the test compound group at the time of grouping and administration, T_{sub.Vt} represents the average tumor volume of the test compound group on day t after administration; C_{sub.V0} represents the average tumor volume of the vehicle group at the time of grouping and administration; C_{sub.Vt} represents the average tumor volume of the

vehicle group on day t after administration. When the tumor regressed, $TGI(\%)_{sub.(tumor\ volume)} = 100\% - (T_{sub.Vt} - T_{sub.V0}) / T_{sub.V0} \times 100\%$. If the tumor shrunk from the initial volume, that was, when $V_{sub.t} < V_{sub.0}$, it was defined as partial tumor regression (PR); if the tumor completely disappeared, it was defined as complete tumor regression (CR).

Experimental Results:

[0768] FIG. 1 shows the curve of tumor volume changing with time in each group in Experimental Example 4, showing the in vivo efficacy of each test substance on SCID-beige mouse xenograft tumor model subcutaneously inoculated with HCC1954 human breast cancer cells. After 21 days of administration, the immune-stimulating antibody conjugate ISAC-1 could significantly inhibit tumor growth, compared with the vehicle control group, the tumor volume TGI was 180.25%, $P < 0.001$, while Trastuzumab monoclonal antibody had no obvious effect (FIG. 1, Table 4). The results showed that in SCID-beige mouse xenograft tumor model subcutaneously inoculated with HCC1954 human breast cancer cells, a single intraperitoneal injection (i.p.) of the immune-stimulating antibody conjugate ISAC-1 showed a very significant anti-tumor effect, apparently better than Trastuzumab monoclonal antibody.
