SYSTEM AND METHOD FOR PROVIDING BREATH ALCOHOL INTERLOCK TECHNOLOGY IN ELECTRIC VEHICLES

Abstract

The improved breath alcohol ignition interlock is for use with a vehicle having a proximity pilot circuit and is of the type adapted to: receive a signal when a vehicle has been enabled for activation of the drivetrain; upon receipt of that signal, trigger a breath tester to prompt for and receive a breath sample; upon receipt of a breath sample, test for alcohol; and upon a determination that the amount of alcohol in the sample is below the legal limit or other threshold, activate a relay. The improvement comprises: a normally open relay coupled to an ignition active circuit of the vehicle for activation thereby; a normally closed relay coupled to the ignition interlock for activation thereby; and a resistor, coupled to the relays in series, between the proximity pilot circuit and ground.

Background/Summary

CROSS REFERENCE TO RELATED APPLICATIONS [0001] This application claims priority to U.S. Provisional Application No. 63/552,957, filed Feb. 13, 2024, the entire contents of which are incorporated herein by reference.

FIELD

[0002] The invention relates to the field of breath alcohol ignition interlock devices.

BACKGROUND

[0003] The installation of breath alcohol testers in internal combustion engine vehicles is well known. Generally, the testers are coupled to a relay that is interposed in the ignition circuit, so that it is impossible to start the vehicle until a breath sample, substantially free of alcohol, has been provided to the device. The installation of breath alcohol testers in electric vehicles is not routine.

SUMMARY

[0004] Forming one aspect of the invention is an improved breath alcohol ignition interlock for use with a vehicle having a proximity pilot circuit, the interlock being of the type adapted to: [0005] receive a signal when a vehicle has been enabled for activation of the drivetrain; [0006] upon receipt of that signal, trigger a breath tester to prompt for and receive a breath sample [0007] upon receipt of a breath sample, test for alcohol; and, upon a determination that the amount of alcohol in the sample is below the legal limit or other threshold, activate a relay.

[0008] The improvement comprises: [0009] a normally open [N/O] relay coupled to an ignition active circuit of the vehicle for activation thereby; [0010] a normally closed [N/C] relay coupled to the ignition interlock for activation thereby; and [0011] a resistor, coupled to the relays in series, between the proximity pilot circuit and ground.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0012] FIG. 1 is a schematic of a prior art vehicle.

[0013] FIG. 2 is an example system according to the present invention.

[0014] FIG. 3 shows the status of the system after a successful install.

[0015] FIG. 4 shows the interlock controller triggering the breath tester to prompt for a breath sample following enablement of the vehicle.

[0016] FIG. 5 shows the breath tester advising the controller by arrow B that a good sample has been received.

[0017] FIG. 6 shows the result of the delivery of the good sample.

[0018] FIG. 7 shows that normally open and normally closed relays return to the rest states upon deactivation of the vehicle.

DESCRIPTION

[0019] The system of the present invention is for use with electric vehicles of the type which include a proximity pilot circuit in the charge port. In this type of vehicle, when a charge cord is coupled to the port, the proximity pilot circuit is connected to ground via a 400 Ohm resistor. The vehicle senses this load and becomes immobile. A schematic of a prior art vehicle is shown in FIG. 1. In the schematic, the vehicle is indicated with reference numeral **100**, the charge port with **102**, the circuitry of the vehicle with **104** and the ground with **106**. The circuit of the vehicle **104** will be

understood to include a low voltage ignition active circuit **108**, that is, a circuit in the vehicle that has voltage when the vehicle has been put into drive. The proximity pilot wire is indicated as **110**. [0020] An example system **20** according to the present invention includes an improved breath alcohol interlock device **22**, a normally open relay **24**, a normally closed relay **26** and a 400 Ohm resistor **28**, as shown in FIG. **2**. The breath alcohol interlock device **22** will be seen to include a breath tester **30** and a controller **32**, and is discussed in more detail below.

[0021] To use the system, an initial step is to identify, through trial and error, the low voltage ignition active circuit. This is easily done by a person of ordinary skill in the art. It will be understood that many vehicles will have multiple low voltage active circuits: a single low voltage active circuit is illustrated for clarity, only. This is easily done by a person of ordinary skill in the art.

[0022] To use the system: [0023] the improved ignition interlock **22** is coupled to vehicle power through, for example, a circuit made available by the vehicle manufacturer for accessories; [0024] the normally open relay **24**, the normally closed relay **26** and the resistor **28** are coupled in series between the ground **106** of the electric vehicle and the proximity pilot wire **110**; [0025] the ignition active circuit **108** is coupled to the normally open relay **24** and to the interlock **22**; and [0026] the normally closed relay **26** is coupled to the interlock **22**

[0027] All of the above is shown in FIG. **3** but for the coupling of the interlock to vehicle power, which is routine to a person of ordinary skill. FIG. **3** will be understood to show the status of the system after a successful install, “ignition off”, with the connection between the ignition active circuit and the interlock, the connection between the ignition active circuit and the normally open relay and the connection between the normally closed relay and the interlock all being “off”, i.e. not energized.

[0028] The improved interlock **22** has the functionality of conventional interlocks, i.e. it is adapted to [0029] receive a signal when a vehicle has been turned on [i.e. detects when an ignition key to a vehicle has been turned away from off]; [0030] upon receipt of that signal, trigger a breath tester to prompt for and receive a breath sample; [0031] upon receipt of a breath sample, test for alcohol; and [0032] upon a determination that the amount of alcohol in the sample is below the legal limit or other threshold [a good sample], activate a relay.

[0033] The improved interlock differs in that: rather than sensing a key turn or its equivalent, its prompt to the breath tester is in response to the ignition active circuit; and rather than triggering an ignition relay to enable operation of a starter upon receipt of a good sample, it causes the normally closed relay to open, and remain open, until such time as the ignition active circuit is deactivated.

[0034] The manner in which the system is used and operates will become apparent upon review of FIGS. **4** to **7**.

[0035] FIG. **4** shows the interlock controller **32** triggering the breath tester **30** to prompt for a breath sample following enablement of the vehicle, i.e. on start up: the prompt being sent to the breath tester is indicated schematically by arrow A. As the vehicle is ignition active mode, the circuits connected to the ignition active circuit **108** are now indicated as “on”.

[0036] FIG. **5** shows the breath tester **30** advising the controller **32** by arrow B that a good sample has been received, i.e. a sample that is, inter alia, below the legal limit.

[0037] FIG. **6** shows the result of the delivery of the good sample. Here, the circuit between the controller **32** and the normally closed relay **26** is “on” such that the normally closed relay is open, thereby disconnecting the proximity pilot circuit **110** from ground **106** and causing the vehicle to disable its immobilizer circuitry and render the vehicle operable for movement.

[0038] FIG. **7** shows that normally open **24** and normally closed **26** relays return to the rest states upon deactivation of the vehicle.

[0039] Whereas a specific embodiment is herein shown and described, modifications are possible. Without limitation in this regard, it is specifically contemplated that the connection between the ignition active circuit and the normally open relay could be, instead of a wire running directly

therebetween as shown, a wire that runs from the ignition active circuit to the interlock controller and then to the normally open relay.

[0040] Further, the normally open relay, the normally closed relay and the resistor could be packaged in a single module, or incorporated into the interlock controller itself.

[0041] Of course, in modern vehicles, there is often no need for a key to be turned.

[0042] Accordingly, the invention should be understood to be limited only by the accompanying claims, purposively construed.

Claims

1. An improved breath alcohol ignition interlock for use with a vehicle having a proximity pilot circuit, the interlock being of the type adapted to: receive a signal when a vehicle has been enabled for activation of the drivetrain; upon receipt of that signal, trigger a breath tester to prompt for and receive a breath sample; upon receipt of a breath sample, test for alcohol; and upon a determination that the amount of alcohol in the sample is below the legal limit or other threshold, activate a relay, the improvement comprising: a normally open relay coupled to an ignition active circuit of the vehicle for activation thereby; a normally closed relay coupled to the ignition interlock for activation thereby; and a resistor, coupled to the relays in series, between the proximity pilot circuit and ground.
