**ABSTRACT**

A cell thawing machine is provided. The cell thawing machine according to one embodiment of the present invention comprises: a thawing unit including a heating block, a heater, an insulation block, and a support, the heating block including a first heating block and a second heating block which form a heating space for heating a container in which a predetermined amount of biological material including cells is stored, the heater being installed in the heating block to provide heat to the heating block, the insulation block being coupled to the heating block to surround the heater, and the supporter being disposed in the heating space to support the lower portion of the container; a driving unit for providing a driving force for linearly moving the first heating block and the second heating block in left and right directions; a sensing unit including a sensor for detecting the state of the container disposed in the heating space, and a mounting member on which the sensor is mounted and which moves in forward and backward directions in connection with the operation of the driving unit; and a control unit for controlling the operations of the thawing unit, the driving unit, and the sensing unit.

## CELL THAWING MACHINE AND METHOD FOR OPERATING SAME

### CROSS REFERENCE TO THE RELATED APPLICATIONS

[0001] This application is the national phase entry of International Application No. PCT/KR2022/008718, filed on Jun. 20, 2022, which is based upon and claims priority to Korean Patent Application No. 10-2021-0082930 filed on Jun. 25, 2021, 10-2021-0098640 filed on Jul. 27, 2021, and 10-2021-0151328 filed on Nov. 5, 2021, the entire contents of which are incorporated herein by reference.

### TECHNICAL FIELD

[0002] The present invention relates to a cell thawing machine and an operating method thereof.

### BACKGROUND

[0003] In general, various biological materials are stored at low temperature after being stored in containers such as vials. For example, plasma and tissue cells are stored at a maximum of -100 degrees Celsius, and stem cells are stored at cryogenic temperatures of up to -165 degrees Celsius by using gaseous liquid nitrogen.

[0004] These biological materials are tested at a temperature higher than the storage temperature of the aforementioned low-temperature state. Accordingly, a thawing process is required to test the biological material.

[0005] To this end, a cell thawing machine has been proposed for thawing a biological material in a low-temperature state by heating a container such as a vial in which the biological material is stored.

[0006] However, conventional cell thawing machines adopt a method of transferring heat while a heating block and a container are in contact with each other. Accordingly, the conventional cell thawing machines have a problem in that it is difficult to uniformly heat the container as a whole, and since the high-temperature heating block directly contacts the container, there is a problem in that the container is cracked or deformed by the high temperature.

[0007] In addition, the conventional cell thawing machine was a method of simply displaying whether the heating block was operating normally through an indicator such as an LED.

[0008] Accordingly, the conventional cell thawing machines have a problem in that the operating temperature of the heating block cannot be easily measured during qualification evaluation to determine whether the heating block operates correctly.

### SUMMARY

[0009] The present invention has been devised in view of the above points, and an object of the present invention is to provide a cell thawing machine which is capable of uniformly heating the container as a whole while securing the heat stability of the container including the biological material during the heating process, and an operation method thereof.

[0010] In addition, another object of the present invention is to provide a cell thawing machine which is capable of increasing energy use efficiency and an operating method thereof.

[0011] Moreover, still another object of the present invention is to provide a cell thawing machine which is capable of conveniently measuring the operating temperature of a heating block during qualification evaluation.

[0012] In order to achieve the above-described objects, the present invention provides a cell thawing machine, including a thawing part including a heating block which includes a first heating block and a second heating block that form a heating space for heating a container in which a predetermined amount of biological material including cells is stored, a heater which is installed in the heating block to provide heat to the heating block, a heat insulating block which is coupled to the heating block to surround the heater, and a pedestal which is configured to support a lower portion of the container in the heating space; a driving part for providing a driving force that linearly moves each of the first heating block and the second heating block in left and right directions; a sensing part including a sensor for detecting the state of the container disposed in the heating space, and a mounting member on which the sensor is mounted and which moves in forward and backward directions in connection with the operation of the driving part; and a control part for controlling the operations of the thawing part, the driving part and the sensing part.

[0013] Meanwhile, the present invention provides a method for operating a cell thawing machine including a heating block including a first heating block and a second heating block which form a heating space for heating a container in which a predetermined amount of biological material including cells is stored through linear movement by a driving force of a motor, and heat the container accommodated in the heating space through heat provided from a heater; and a sensor for changing a position in connection with the linear movement of the heating block and detecting the state of the container disposed in the heating space, the method including a first step of preheating the first heating block and the second heating block to a predetermined temperature by driving the heater while one surface of the first heating block and one surface of the second heating block facing each other are in contact with each other; a second step of heating the container disposed in the heating space to thaw the biological material while the first heating block and the second heating block are changed to a heating position forming the heating space; and a third step of changing the first and second heating blocks to a standby position by moving the same in a direction of moving away from the heating position such that the container disposed in the heating space can be removed, wherein in the second step, the container disposed in the heating space is heated by heat transferred from the first heating block and the second heating block in a non-contact manner without contacting the first heating block and the second heating block.

[0014] According to the present invention, the container can be uniformly heated by heating the container in a non-contact heating manner by using radiant heat, and it is possible to prevent cracks or thermal deformation of the container that may occur during heating by conductive heat in advance.

[0015] In addition, according to the present invention, since the temperature of the heating block can be maintained to be constant, a plurality of containers can be sequentially thawed. Through this, the present invention can improve

energy consumption efficiency, because it is possible to thaw a plurality of containers while reducing the reuse waiting time for thawing containers.

[0016] Furthermore, according to the present invention, when the upper cover is separated, the sensor insertion hole for qualification evaluation is exposed to the outside such that it is possible to easily perform qualification evaluation.

#### BRIEF DESCRIPTION OF THE DRAWINGS

[0017] FIG. 1 is a view showing a cell thawing machine according to one embodiment of the present invention;

[0018] FIG. 2 is a view of FIG. 1 viewed from another direction;

[0019] FIG. 3 is a view in which the housing is separated from FIG. 1;

[0020] FIG. 4 is a view showing the cell thawing machine according to the first embodiment of the present invention, showing a state in which the housing and circuit board are removed from FIG. 3;

[0021] FIG. 5 is a view of FIG. 4 viewed from another direction;

[0022] FIG. 6 is a view in which some components are separated from FIG. 4;

[0023] FIG. 7 is an enlarged view of a part of FIG. 5, in which portions of the first heating block and the second heating block are cut in a standby position;

[0024] FIG. 8 is a view showing a portion of the cell thawing machine according to the first embodiment of the present invention in a state where the heating block is disposed in a heating position;

[0025] FIG. 9 is a view showing the configuration of a sensing part applied to the cell thawing machine according to one embodiment of the present invention, showing the position of a roller member in a state where the heating block is disposed at a heating position;

[0026] FIG. 10 is a view showing the configuration of a sensing part applied to the cell thawing machine according to one embodiment of the present invention, showing the position of a roller member in a state where the heating block is placed in a standby position;

[0027] FIG. 11 is a view showing the arrangement relationship of the sensing part, the heating block and the container corresponding to the state of FIG. 9, showing a state in which the first heating block, the first heat insulating block and the first guide block are removed;

[0028] FIG. 12 is a view showing the arrangement relationship of the sensing part and the heating block corresponding to the state of FIG. 10, showing a state in which the first heating block, the first heat insulating block and the first guide block are removed;

[0029] FIG. 13 is an operating state diagram of the cell thawing machine according to the first embodiment of the present invention, and is a partial cross-sectional view of the standby position at the time of initial operation, as viewed from the A-A direction of FIG. 8;

[0030] FIG. 14 is an operating state diagram showing a state in which the heating block is preheated in the cell thawing machine according to the first embodiment of the present invention, and is a partial cross-sectional view as viewed from the A-A direction of FIG. 8;

[0031] FIG. 15 is an operating state diagram showing the process of loading a container into the cell thawing machine

according to the first embodiment of the present invention, and is a partial cross-sectional view as viewed from the A-A direction of FIG. 8;

[0032] FIG. 16 is an operating state diagram of the cell thawing machine according to the first embodiment of the present invention, and is a partial cross-sectional view of a state in which the container is heated in the heating position, as viewed from the A-A direction in FIG. 8;

[0033] FIG. 17 is an operating state diagram of the cell thawing machine according to the first embodiment of the present invention, and is a partial cross-sectional view of the process of removing the container from the standby position, as viewed from the A-A direction in FIG. 8;

[0034] FIG. 18 is a view showing a cell thawing machine according to the second embodiment of the present invention, showing a state in which the upper cover is separated from the state in which the cover is removed in FIG. 1;

[0035] FIG. 19 is a cross-sectional view in the B-B direction of FIG. 18, extracting a thawing part;

[0036] FIG. 20 is a view showing the cell thawing machine according to the second embodiment of the present invention, showing a state in which the housing and circuit board are removed from FIG. 3;

[0037] FIG. 21 is a view of FIG. 20 viewed from another direction;

[0038] FIG. 22 is a view in which some components are separated from FIG. 20;

[0039] FIG. 23 is an enlarged view of a part of FIG. 21, in which portions of the first heating block and the second heating block are cut in a standby position;

[0040] FIG. 24 is a view showing a part of the cell thawing machine according to the second embodiment of the present invention in a state where the heating block is disposed at a heating position;

[0041] FIG. 25 is an operating state diagram of the cell thawing machine according to a second embodiment of the present invention, and is a partial cross-sectional view of the standby position when initially driven, as viewed from the B-B direction of FIG. 24;

[0042] FIG. 26 is an operating state diagram showing a state in which the heating block is preheated in the cell thawing machine according to the second embodiment of the present invention, and is a partial cross-sectional view as viewed from the C-C direction of FIG. 24;

[0043] FIG. 27 is an operating state diagram showing the process of loading a container into the cell thawing machine according to the second embodiment of the present invention, and is a partial cross-sectional view as viewed from the C-C direction of FIG. 24;

[0044] FIG. 28 is an operating state diagram of the cell thawing machine according to the second embodiment of the present invention, and is a partial cross-sectional view of the state in which the container is heated in the heating position, as viewed from the direction C-C in FIG. 24;

[0045] FIG. 29 is an operating state diagram of the cell thawing machine according to the second embodiment of the present invention, and is a partial cross-sectional view of the process of removing the container from a standby position, as viewed from the C-C direction in FIG. 24; and

[0046] FIG. 30 is a block diagram showing the operating method of a cell thawing machine according to one embodiment of the present invention.

# DETAILED DESCRIPTION OF THE EMBODIMENTS

[0047] Hereinafter, with reference to the accompanying drawings, the exemplary embodiments of the present invention will be described in detail so that those skilled in the art can easily practice the present invention. The present invention may be embodied in many different forms and is not limited to the exemplary embodiments set forth herein. In order to clearly describe the present invention in the drawings, parts that are irrelevant to the description are omitted, and the same reference numerals are assigned to the same or similar components throughout the specification.

[0048] The cell thawing machines 100, 200 according to one embodiment of the present invention may heat and thaw biological materials in a low-temperature state (e.g., frozen state) contained in a container 10.

[0049] Herein, the biological material may include cells, which are the structural basic unit of an organism, and the container 10 may be a known laboratory container or a container for medical use, such as a vial, a beaker or a test tube.

[0050] In addition, as illustrated in FIG. 1, the container 10 may include a container main body 12 in which the biological material is accommodated, a cap part 14 for covering an open upper portion of the container main body 12, and a flange part 16 which is formed to protrude from a lower portion of the container main body 12, and a biological material of about 2 mL capacity may be contained in the container main body 12. However, the shape of the container 10 and the capacity of the biological material contained in the container main body 12 are not limited thereto and may be changed into various shapes depending on design conditions.

[0051] In this case, the cell thawing machines 100, 200 according to one embodiment of the present invention may heat the container 10 uniformly as a whole by heating the container 10 in a non-contact heating manner through radiant heat and/or convection heat, and it is possible to prevent cracks or thermal deformation of the container 10 that may occur during contact heating by conductive heat in advance.

[0052] To this end, as illustrated in FIGS. 1 to 6 and 18 to 22, the cell thawing machines 100, 200 according to one embodiment of the present invention include a housing 110, a thawing part 120, a driving part 130, a sensing part 140 and a control part 150.

[0053] As illustrated in FIGS. 1 to 3, the housing 110 may form an outer surface of the cell thawing machine 100, 200, and it may be formed in a box shape such that the thawing part 120, the driving part 130, the sensing part 140 and the control part 150 can be disposed therein.

[0054] The housing 110 may be composed of one member or may be composed of a plurality of members, and the plurality of members may be detachably coupled.

[0055] For example, as illustrated in FIG. 3, the housing 110 may include a box-shaped main body 111, a lower cover 112 for covering an open lower portion of the main body 111, a rear cover 113 for covering an open rear surface of the main body 111, and an upper cover 114 for covering an upper portion of the main body 111.

[0056] In this case, the thawing part 120, the driving part 130, the sensing part 140 and the control part 150 may be disposed inside the main body 111.

[0057] In this case, the housing 110 may include an inlet 115 which is formed to penetrate a predetermined area such

that the container 10 can be inserted into the main body 111, and the inlet 115 may be covered through a cover 116.

[0058] Herein, the inlet 115 may be formed to penetrate the housing 110 so as to be located at a position corresponding to a heating space 121 to be described below.

[0059] For example, the inlet 115 may be formed to penetrate the upper cover 114 to communicate with a heating space 121 formed in the thawing part 120 at a heating position to be described below. Through this, when the container 10 is inserted into the inlet 115, the cap part 14 of the container 10 may be exposed to the outside through the inlet 115, and the remaining portion except for the cap part 14 may be inserted into the heating space 121.

[0060] In addition, as illustrated in FIGS. 1 and 18, a manipulation part 117 for manipulating the operation of the cell thawing machines 100, 200 according to one embodiment of the present invention, and a display 118 for displaying the operating state of the cell thawing machines 100, 200 may be provided on one side of the housing 110.

[0061] Such a manipulation part 117 may be an interface for transmitting an input signal to the control part 150 through user manipulation.

[0062] Herein, the manipulation part 117 may be configured with a known press-type physical button or capacitive touch button.

[0063] In addition, although it may be provided separately from the display 118, it may be provided in an integrated form with the display 118.

[0064] Moreover, the display 118 may output information on the overall operating state of the cell thawing machines 100, 200 operated through the control part 150 (e.g., the operating status such as the temperature of the heating blocks 122a, 122b, the surface temperature of the container 10, thawing or completion of thawing, or thawing progress time), date and time at the time of thawing, an error message such as sensor or heater failure, which will be described below, and the like.

[0065] Through this, the user may transmit input signals, such as operation and stop of the cell thawing machines 100, 200, thawing temperature adjustment and thawing time adjustment, to the control part 150 through manipulation of the manipulation part 117, and the display 118 may output information on the overall state of the cell thawing machines 100, 200 through the control part 150.

[0066] Moreover, as illustrated in FIG. 2, the cell thawing machines 100, 200 may include at least one communication port 119 that is provided to be exposed to the outside from one side of the housing 110, and the communication port 119 may be electrically connected to the control part 150.

[0067] For example, the communication port 119 may include a LAN port 119a for communication with communication device such as an external network device or a PC, and a USB port 119b for inputting or outputting data, and the communication port 119 may be mounted on the rear cover 113 so as to be electrically connected to the control part 150.

[0068] In this case, when the cell thawing machines 100, 200 according to one embodiment of the present invention are connected to the external network device or communication device such as a PC through the communication port 119, the control part 150 may be time-synchronized with communication device such as the external network device or PC.

[0069] For example, when the cell thawing machines 100, 200 are connected to a PC such as a laptop computer, the cell

thawing machines **100, 200** may be synchronized with the date and time of the PC by using a synchronization program installed in the PC.

[0070] Through this, the cell thawing machines **100, 200** according to one embodiment of the present invention may be synchronized with the local time of the region where thawing is performed when in use, and the local time of the region may be output through the display **118**.

[0071] As a result, the cell thawing machines **100, 200** according to one embodiment of the present invention may store history information about the exact time of thawing of the biological material contained in the container **10**, and the user may confirm the exact thawing time of the biological material contained in the container **10** through the history information.

[0072] Additionally, information related to thawing may be stored in the cell thawing machines **100, 200** themselves or may be stored in a synchronization program of a communication device that is connected through the communication port **119**.

[0073] In this case, although the information related to thawing stored in the cell thawing machines **100, 200** or the synchronization program may be stored by date, a thawing history may be stored for each thawing case, and the thawing history may include the local time of the region where the thawing is performed.

[0074] The thawing part **120** may heat the container **10** while the container **10** introduced into the housing **110** through the inlet **115** is accommodated in a heating space **121**.

[0075] To this end, as illustrated in FIGS. **4** to **8** and **20** to **24**, the thawing part **120** may include heating blocks **122a, 122b** for forming a heating space **121** for accommodating the container **10**, heaters **123a, 123b** which are installed on the heating blocks **122a, 122b** to provide heat to the heating blocks **122a, 122b**, and heat insulating blocks **124a, 124b** which are coupled to the heating blocks **122a, 122b** so as to surround the heaters **123a, 123b**, and a pedestal **125** for supporting a lower portion of the container **10** in the heating space **121**.

[0076] Accordingly, when the container **10** is introduced into the housing **110** through the inlet **115**, the lower portion of the container **10** may be supported through a pedestal **125**, and the container **10** may be surrounded through the heating blocks **122a, 122b** while being accommodated in the heating space **121** (refer to FIGS. **16, 19** and **28**).

[0077] In this case, as illustrated in FIGS. **6, 7, 22** and **23**, the heating blocks **122a, 122b** may include arrangement grooves **126a, 126b** which are formed to be drawn inward on one surface, and the heaters **123a, 123b** may be inserted into the arrangement grooves **126a, 126b**, and the heat insulating blocks **124a, 124b** may be coupled to the heating blocks **122a, 122b** so as to completely cover the arrangement grooves **126a, 126b** while the heaters **123a, 123b** are inserted into the arrangement grooves **126a, 126b**.

[0078] Herein, the heating blocks **122a, 122b** may be made of a material having thermal conductivity such as metal, and the heat insulating blocks **124a, 124b** may be made of a material having heat insulation property.

[0079] Accordingly, when the heaters **123a, 123b** generate heat, the heating blocks **122a, 122b** may be heated by the heat generated from the heaters **123a, 123b**, and the heat generated from the heaters **123a, 123b** may be concentrated toward the heating blocks **122a, 122b** by limiting the direc-

tion of heat movement through the heat insulating blocks **124a, 124b**, and the heat transferred from the heaters **123a, 123b** to the heating blocks **122a, 122b** may be transferred toward the heating space **121**.

[0080] As a result, the container **10** may be heated by the heat provided from the heating blocks **122a, 122b**, and the biological material stored in the container **10** may be thawed by the heat.

[0081] Moreover, since the heat generated from the heaters **123a, 123b** may be concentrated toward the heating blocks **122a, 122b** by limiting the direction of heat movement through the heat insulating blocks **124a, 124b**, the cell thawing machines **100, 200** according to one embodiment of the present invention may improve energy consumption efficiency.

[0082] Additionally, since the container **10** accommodated in the heating space **121** may be heated by using the heat of the heating blocks **122a, 122b** that are heated to a constant temperature by the heat transferred from the heaters **123a, 123b**, the circumferential surface of the container **10** may be heated to a uniform temperature. Herein, the circumferential surface of the container **10** may be the circumferential surface of the container main body **12** excluding the cap part **14** and the flange part **16**.

[0083] In this case, as illustrated in FIGS. **4** and **20**, the thawing part **120** may include temperature sensors **128a, 128b** which are installed on the heating blocks **122a, 122b** so as to measure the temperature of the heating blocks **122a, 122b**. Herein, the temperature sensors **128a, 128b** may be known contact-type temperature sensors such as thermocouples, resistance thermometers (RTDs) and thermistors, and the temperatures of the heating blocks **122a, 122b** measured through the temperature sensors **128a, 128b** may be transmitted to the control part **150**.

[0084] Accordingly, the control part **150** may control the driving of the heaters **123a, 123b** based on the temperature information measured by the temperature sensors **128a, 128b** to maintain the temperatures of the heating blocks **122a, 122b** to constant temperatures. For example, the control part **150** may maintain the temperatures of the heating blocks **122a, 122b** to be constant by controlling the driving of the heaters **123a, 123b** through PID control.

[0085] Moreover, the control part **150** may prevent overheating of the heating blocks **122a, 122b** by controlling driving of the heaters **123a, 123b** based on the temperature information measured by the temperature sensors **128a, 128b**.

[0086] In the present invention, the heaters **123a, 123b** may be ceramic heaters to secure reliability and improve the lifespan cycle of products even under operating conditions in which heating and cooling are repeatedly performed, but the present invention not limited thereto, and various known heaters may be applied.

[0087] Meanwhile, the heating space **121** may be provided in a shape corresponding to the shape of the container **10**, and the heating space **121** may be formed through at least two heating blocks **122a, 122b**.

[0088] As a specific example, as illustrated in FIGS. **4** to **6** and **20** to **22**, the heating blocks **122a, 122b** may include a first heating block **122a** and a second heating block **122b** that are disposed such that surfaces thereof face each other, and the heating space **121** may be formed through a pair of opposing surfaces **127a, 127b** that are formed to be drawn

on surfaces facing each other on the first heating block **122a** and the second heating block **122b**, respectively.

[0089] Herein, the pair of opposing surfaces **127a**, **127b** may be drawn inward to have a shape corresponding to the circumferential surface of the container **10**.

[0090] For example, when the container **10** is formed in the shape of a cylinder, the pair of opposing surfaces **127a**, **127b** may be arc-shaped curved surfaces, and when the container **10** is formed in the shape of a square column, the pair of opposing surfaces **127a**, **127b** may be formed as bent surfaces having a substantially 'c' cross-sectional shape.

[0091] Accordingly, when the container **10** is introduced into the heating space **121** through the inlet **115**, the container **10** may be completely surrounded by a pair of opposing surfaces **127a**, **127b** on which the circumferential surface thereof defines the heating space **121**.

[0092] As a result, the circumferential surface of the container **10** accommodated in the heating space **121** may be uniformly heated by the heat provided from the first heating block **122a** and the second heating block **122b**.

[0093] In this case, each of the first heating block **122a** and the second heating block **122b** may include arrangement grooves **126a**, **126b** that are formed to be drawn inward on one surface thereof, respectively, and the heaters **123a**, **123b** may include a first heater **123a** and a second heater **123b** that are disposed to be inserted into the arrangement groove **126a** formed in the first heating block **122a** and the arrangement groove **126b** formed in the second heating block **122b**, respectively.

[0094] In addition, the heat insulating blocks **124a**, **124b** may include a first heat insulating block **124a** and a second heat insulating block **124b**, and the first heat insulating block **124a** may be coupled to the first heating block **122a** so as to completely cover the arrangement groove **126a** while the first heater **123a** is inserted into the arrangement groove **126a** of the first heating block **122a**, and the second heat insulating block **124b** may be coupled to the second heating block **122b** so as to completely cover the arrangement groove **126b** while the second heater **123b** is inserted into the arrangement groove **126b** of the second heating block **122b**.

[0095] Moreover, the temperature sensors **128a**, **128b** may include a first temperature sensor **128a** which is installed in the first heating block **122a** to measure the temperature of the first heating block **122a**, and a second temperature sensor **128b** which is installed in the second heating block **122b** to measure the temperature of the second heating block **122b**.

[0096] Accordingly, the heat generated from the first heater **123a** may heat the first heating block **122a**, and the heat generated from the second heater **123b** may heat the second heating block **122b**, and the control part **150** may control the driving of the first heater **123a** and the second heater **123b** based on the temperature information measured by the first temperature sensor **128a** and the second temperature sensor **128b** such that it is possible to maintain the temperatures of the first heating block **122a** and the second heating block **122b** to be constant.

[0097] In this case, the control part **150** may control the operations of the first heater **123a** and the second heater **123b** together based on the temperature information measured through the first temperature sensor **128a** and the second temperature sensor **128b**, or the control part **150** may individually control the operations of the first heater **123a** and the second heater **123b** based on the temperature infor-

mation measured through the first temperature sensor **128a** and the second temperature sensor **128b**.

[0098] Through this, even if the heating blocks **122a**, **122b** include the first heating block **122a** and the second heating block **122b** in the cell thawing machines **100**, **200** according to one embodiment of the present invention, the temperatures of the first heating block **122a** and the second heating block **122b** may be precisely controlled through the control of the control part **150**.

[0099] Accordingly, since the first heating block **122a** and the second heating block **122b** may be maintained at the same temperature without temperature deviation through the control part **150**, the circumferential surface of the container **10** may be uniformly heated.

[0100] Moreover, when the control part **150** individually controls the driving of the first heater **123a** and the second heater **123b**, the user may immediately check an anomaly of the corresponding part based on the information output through the display **118**, and take appropriate action on the corresponding part in which the abnormality occurred.

[0101] For example, when any one of the heaters **123a**, **123b** that are respectively installed in the first heating block **122a** and the second heating block **122b** or any one of the temperature sensors **128a**, **128b** that are respectively installed in the first heating block **122a** and the second heating block **122b** does not operate normally, the user may immediately check an abnormality of the corresponding part based on the information output through the display **118**, and take appropriate action on the corresponding part in which the abnormality has occurred.

[0102] Meanwhile, in the cell thawing machines **100**, **200** according to one embodiment of the present invention, while the container **10** accommodated in the heating space **121** does not contact the heating block **122a**, **122b**, the container **10** may be heated by the heat transferred from the heating block **122a**, **122b** in a non-contact manner.

[0103] For example, while the container **10** is inserted into the heating space **121**, the circumferential surface of the container **10** may be spaced apart by a certain interval from the opposing surface **127a** of the first heating block **122a** and the opposing surface **127b** of the second heating block **122b** forming the heating space **121**.

[0104] That is, as illustrated in FIGS. **16** and **28**, while the container **10** is inserted into the heating space **121** and the lower portion of the container **10** is supported through the pedestal **125**, a gap (d) may be formed between the pair of opposing surfaces **127a**, **127b** and the outer surface of the container **10**.

[0105] Accordingly, the heat stored in the first heating block **122a** and the second heating block **122b** may be transferred to the relatively low-temperature container **10** through convection and/or radiation instead of conduction.

[0106] As a result, since the cell thawing machines **100**, **200** according to one embodiment of the present invention may heat the circumferential surface of the container **10** through heat transfer using convection and/or radiation, the circumferential surface of the container **10** may be uniformly heated through convective heat and/or radiant heat transmitted from the heating blocks **122a**, **122b**.

[0107] That is, compared to the case where the container **10** and the heating blocks **122a**, **122b** are in direct contact and the container **10** is heated through conduction heat, the cell thawing machines **100**, **200** according to one embodiment of the present invention may uniformly heat the

circumferential surface of the container through convective heat and/or radiant heat, and thus, it is possible to prevent the concentration of heat in a local location of the container 10.

[0108] Moreover, in the cell thawing machines 100, 200 according to one embodiment of the present invention, even if the container 10 is made of a glass or plastic material that is vulnerable to high-temperature heat, the first heating block 122a and the second heating block 122b do not come into direct contact with the container 10, and thus, it is possible to prevent cracks or thermal deformation of the container that may occur due to heat when in direct contact with a high-temperature object.

[0109] In the present invention, the gap (d) between the pair of opposing surfaces 127a, 127b forming the heating space 121 and the outer surface of the container 10 may be 0.2 mm to 0.3 mm, but the present invention is limited thereto, and the size of the gap (d) may be appropriately changed depending on the overall size of the container 10.

[0110] In this case, at least any one of the first heating block 122a and the second heating block 122b may be linearly moved reciprocally in a straight line, and the heating space 121 may be formed when the first heating block 122a and the second heating block 122b are disposed to be located in nearby positions through the linear movement of at least any one of the first heating block 122a and the second heating block 122b. The detailed description thereof will be described below.

[0111] Meanwhile, as illustrated in FIGS. 6, 7, 22 and 23, the pedestal 125 for supporting a lower portion of the container 10 may include a seating groove 125a which is formed on one surface supporting a lower portion of the container 10 in order to allow a lower edge of the container 10 to be inserted, and a protruding member 125d which is formed to protrude at a certain height such that the lower surface of the container 10 can be spaced apart at a certain height from one surface of the pedestal 125.

[0112] When the container 10 is inserted into the inlet 115, the seating groove 125a may stably support the container 10 by fixing the lower edge of the container 10.

[0113] In addition, when the container 10 is inserted into the inlet 115, the protruding member 125d may support the lower surface of the container 10 such that the lower surface of the container 10 is spaced apart at a certain height from one surface of the pedestal 125.

[0114] To this end, the seating groove 125a may be formed in a shape corresponding to a flange part 16 such that the flange part 16 formed along the lower edge of the container 10 can be inserted therein, and as illustrated in FIGS. 9 and 10, the seating groove 125a may be formed to be located outside the protruding member 125d along the circumferential direction of the protruding member 125d.

[0115] Accordingly, when the container 10 is inserted into the inlet 115, the lower surface of the container 10 may be supported by one surface of the protruding member 125d, and the flange part 16 may be inserted into the seating groove 125a, and the container 10 in which the flange part 16 is inserted into the seating groove 125a may maintain an upright state without tilting in any direction.

[0116] As a result, while the container 10 disposed in the heating space 121 is correctly positioned such that the circumferential surface thereof faces a pair of opposing surfaces 127a and 127b forming the heating space 121 in the heating space 121, it may maintain a uniform gap with the pair of opposing surfaces 127a, 127b.

[0117] The driving part 130 may linearly move the heating blocks 122a, 122b in left and right directions. For example, as described above, when the heating blocks 122a, 122b include a first heating block 122a and a second heating block 122b, the driving part 130 may linearly move at least any one of the first heating block 122a and the second heating block 122b reciprocally in the left and right directions.

[0118] As a non-limiting example, when the heating blocks 122a, 122b include a first heating block 122a and a second heating block 122b, the driving part 130 may linearly move the first heating block 122a and the second heating block 122b reciprocally in the left and right directions, respectively.

[0119] Through this, as illustrated in FIGS. 16, 26 and 28, the cell thawing machines 100, 200 according to one embodiment of the present invention may be changed to a heating position in which the first heating block 122a and the first heating block 122a are disposed to be close to each other through the driving of the driving part 130, and a standby position in which the first heating block 122a and the second heating block 122b are disposed to be spaced apart from each other at a gap through the driving of the driving part 130 as illustrated in FIGS. 13, 15, 17, 25, 27 and 29.

[0120] Accordingly, as illustrated in FIGS. 16 and 28, when the first heating block 122a and the second heating block 122b are located at the heating position, a heating space 121 for accommodating the container 10 to heat the container 10 may be formed between the opposing surface 127a of the first heating block 122a and the opposing surface 127b of the second heating block 122b.

[0121] In addition, as illustrated in FIGS. 15, 17, 27 and 29, when the first heating block 122a and the second heating block 122b are located in the standby position, a gap between the opposing surface 127a of the first heating block 122a and the opposing surface 127b of the second heating block 122b may be widened. Through this, the user may easily introduce the container 10 to be disposed between the first heating block 122a and the second heating block 122b or may easily remove the container 10 which is disposed between the first heating block 122a and the second heating block 122b.

[0122] To this end, as illustrated in FIGS. 4 to 6 and 20 to 22, the driving part 130 may include a motor 131 for providing a driving force, a rotating member 132 which is axially coupled to a rotating shaft 131a of the motor 131, and a power transmission member for interconnecting the rotating member 132 and the thawing part 120 so as to linearly move the first heating block 122a and the second heating block 122b, respectively, when the motor 131 is driven.

[0123] In addition, the power transmission member may include guide blocks 134a, 134b which are fixedly coupled to the heat insulating blocks 124a, 124b, guide rails 135 for guiding linear movement of the guide blocks 134a, 134b, a moving member 136 which moves up and down in the top and down directions along the rotating member 132 when the motor 131 is driven, and link members 137a, 137b for linking the guide blocks 134a, 134b and the moving member 136 to each other.

[0124] As a specific example, the guide blocks 134a, 134b may include a first guide block 134a which is fixedly coupled to the first heat insulating block 124a and a second guide block 134b which is fixedly coupled to the second heat insulating block 124b, the first guide block 134a and the

second guide block **134b** may be coupled to the guide rail **135** so as to be slidably movable.

[0125] In addition, the link members **137a**, **137b** may include a first link member **137a** for linking the moving member **136** and the first guide block **134a** to each other, and a second link member **137b** for linking the moving member **136** and the second link member **137b** to each other.

[0126] In this case, the cell thawing machines **100**, **200** according to one embodiment of the present invention may further include a base **161**, a mounting table **162**, a support bar **163** and a support **164** that are disposed inside the housing **110**.

[0127] That is, as illustrated in FIGS. **6** and **22**, a mounting table **162** may be fixedly coupled to an upper surface of the base **161**, and the motor **131** may be fixedly coupled to one side of the mounting table **162** via a coupling base **165**, and the rotating member **132** which is axially coupled to a rotating shaft **131a** of the motor **131** may be rotatably coupled to the mounting table **162**.

[0128] In addition, the plate-shaped support **164** having a predetermined area may be disposed at a certain interval from an upper portion from the base **161** through at least one support bar **163** having a predetermined length and one end of which is fixedly coupled to the base **161**, and the guide rail **135** and the pedestal **125** may be fixedly coupled to one surface of a support **164**.

[0129] Moreover, the first guide block **134a** and the second guide block **134b** may be slidably coupled to the guide rail **135**, and the first heat insulating block **124a** may be fixedly coupled to the first guide block **134a**, and the second heat insulating block **124b** may be fixedly coupled to the second guide block **134b**.

[0130] Herein, the rotating member **132** may be a screw bar having a predetermined length and having one end axially coupled to a rotating shaft **131a** of the motor **131**, and the moving member **136** may be screw-coupled to the rotating member **132** to be movable.

[0131] In addition, the support **164** may include a through-hole **164a** having a long hole through which the first link member **137a** and the second link member **137b** may respectively pass.

[0132] Moreover, both ends of the first link member **137a** may be linked to the rotating member **132** and the first guide block **134a**, respectively, and both ends of the second link member **137b** may be linked to the rotating member **132** and the second guide block **134b**, respectively.

[0133] Accordingly, as illustrated in FIGS. **13** to **17** and **25** to **29**, when the rotating member **132** which is axially coupled to the rotating shaft **131a** rotates when the motor **131** is driven, the moving member **136** may move up and down by screw movement along the rotating member **132**, and the first guide block **134a** and the second guide block **134b** which are respectively linked to the moving member **136** may be linearly moved in the left and right directions along the guide rail **135** through the ascending and descending of the moving member **136**.

[0134] As a result, the first heat insulating block **124a** and the second heat insulating block **124b**, which are fixedly coupled to the first guide block **134a** and the second guide block **134b**, respectively, may be linearly moved in the left and right directions in the same manner as the first guide block **134a** and the second guide block **134b**, and the first heating block **122a** and the second heating block **122b**, which are fixedly coupled to the first heat insulating block

**124a** and the second heat insulating block **124b**, respectively, may also be linearly moved in the left and right directions.

[0135] Through this, in the cell thawing machines **100**, **200** according to one embodiment of the present invention, the first heating block **122a** and the second heating block **122b** may be changed to a heating position in which the first heating block **122a** and the second heating block **122b** are disposed to be close to each other through the driving of the driving part **130**, and may be changed to a standby position in which the first heating block **122a** and the second heating block **122b** are disposed to be spaced apart from each other at an interval through the driving of the driving part **130**.

[0136] Moreover, when the cell thawing machines **100**, **200** according to one embodiment of the present invention are changed from the standby position to the heating position through the control of the control part **150**, a lower portion of the container **10**, which is accommodated in the heating space **121**, may be located at a relatively higher position than the lower surfaces of the first heating block **122a** and the second heating block **122b** through the protruding member **125d**.

[0137] Accordingly, the container **10** which is disposed in the heating space **121** may be disposed in a state where the circumferential surface faces a pair of opposing surfaces **127a**, **127b** forming the heating space **121**.

[0138] The drawings and description illustrate and describe that the rotational movement of the motor **131** is changed to the linear movement of the first guide block **134a** and the second guide block **134b** through mutual coupling of the rotating member **132**, the moving member **136** and the link members **137a**, **137b**, but the present invention is not limited thereto, and various known structures such as a ball screw structure may all be applied as long as rotational movement can be converted into linear movement.

[0139] In this case, the cell thawing machines **100**, **200** according to one embodiment of the present invention may further include a position detecting means for detecting the positions of the heating blocks **122a**, **122b**.

[0140] For example, in the cell thawing machine **100** according to one embodiment of the present invention, the position detecting means may be a limit switch **170** for detecting the positions of the heating blocks **122a**, **122b** through contact with the heat insulating blocks **124a**, **124b**.

[0141] As illustrated in FIG. **6**, the limit switch **170** may be installed on one surface of the support **164**, and may detect the position of the second heating block **122b** through contact with the second heat insulating block **124b**, and the information detected through the limit switch **170** may be provided to the control part **150**.

[0142] As a specific example, as illustrated in FIGS. **7** and **8**, the limit switch **170** may include a switch box **171** which is fixedly installed on one surface of the support **164**, an operating lever **172** which performs a hinge operation on one side of the switch box **171**, and a roller **173** which is rotatably coupled to one end of the operating lever **172**.

[0143] Accordingly, in the limit switch **170**, when the roller **173** contacts the second heat insulating block **124b** and the operating lever **172** operates, the switch box **171** may be operated, and information on whether the switch box **171** is operated may be transmitted to the control part **150**.

[0144] Specifically, as described above, when the first heating block **122a** and the second heating block **122b** are changed from the heating position to the standby position

through the driving of the driving part 130, the second heat insulating block 124b may move together with the second heating block 122b.

[0145] Through this, the second heat insulating block 124b may come into contact with the roller 173, and as illustrated in FIG. 7, when the second heating block 122b is completely moved to the standby position, the operating lever 172 may be operated such that the switch box 171 can be operated.

[0146] In this case, the control part 150 determines that the second heating block 122b is positioned in the standby position and controls the driving of the motor 131 such that it is possible to prevent the second heating block 122b from moving excessively.

[0147] In addition, as illustrated in FIG. 8, when the first heating block 122a and the second heating block 122b are changed from the standby position to the heating position through the driving of the driving part 130, the second heat insulating block 124b is moved together with the second heating block 122b such that the contact state between the second heat insulating block 124b and the roller 173 can be released.

[0148] The drawings and description exemplify a hinge roller-type limit switch as a position detection means for detecting the position of the second heating block 122b, but the present invention is not limited thereto, and various known limit switches, such as lever-type limit switches and pin-type limit switches, may all be employed.

[0149] As another example, in the cell thawing machine 200 according to one embodiment of the present invention, the position detection means may be a position detection sensor 270 for detecting the positions of the heating blocks 122a, 122b that linearly move in left and right directions through the driving of the driving part 130.

[0150] Such a position detection sensor 270 may be a non-contact position detection sensor.

[0151] As a specific example, the non-contact position detection sensor 270 may be a known photo-microsensor. As a non-limiting example, as illustrated in FIGS. 20 to 21, the non-contact position detection sensor 270 may include a photosensor 272 which is installed on one surface of the support 164, and a detection bar 274, one end of which is fixedly installed in the second heat insulating block 124b.

[0152] Accordingly, when the detection bar 274 approaches the photosensor 272 through linear movement of the second heating block 122b and the second heat insulating block 124b, the photosensor 272 may detect the position of the second heating block 122b through the detection bar 274, and the information detected through the position detection sensor 270 may be provided to the control part 150.

[0153] As a result, the control part 150 may accurately detect the position of the second heating block 122b through the non-contact position detection sensor 270, and may accurately check the origin of the motor 131.

[0154] Specifically, as described above, when the first heating block 122a and the second heating block 122b are changed from the heating position to the standby position through the driving of the driving part 130, the second heat insulating block 124b may move together with the second heating block 122b.

[0155] Through this, the detection bar 274, which is fixed to the second heat insulating block 124b, may move toward the photosensor 272, and as illustrated in FIG. 23, when the

second heating block 122b is completely moved to the standby position, a partial length of the detection bar 274 may enter a groove portion that is formed in the photosensor 272.

[0156] In this case, the control part 150 determines that the second heating block 122b is correctly located in the standby position and controls the driving of the motor 131 such that it is possible to prevent the second heating block 122b from moving excessively.

[0157] In addition, as illustrated in FIG. 24, when the first heating block 122a and the second heating block 122b are changed from the standby position to the heating position through the driving of the driving part 130, the detection bar 274, which is fixed to second heat insulating block 124b, may move away from the photosensor 272.

[0158] The drawings and description exemplify a non-contact sensor as a method for detecting the position of the second heating block 122b, but the present invention is not limited thereto, and various known position detection sensors may be employed as long as the position of the heating block 122 can be detected.

[0159] The sensing part 140 may check the state of the container 10 disposed in the heating space 121. For example, when the thawing part 120 is located at the heating position, the sensing part 140 may detect the surface temperature of the container 10 that is disposed in the heating space 121, and provide the detected result to the control part 150.

[0160] Accordingly, the control part 150 may output information on the container 10 detected through the sensing part 140 at the heating position to the display 118.

[0161] As a result, the user may check the thawing process of the biological material contained in the container 10 in real time through the information output from the display 118, and may monitor whether the biological material is thawing within an appropriate temperature range.

[0162] To this end, as illustrated in FIGS. 6, 7, 22 and 23, the sensing part 140 may include a sensor 141 for checking the state of the container 10 disposed in the heating space 121, and a mounting member 142 on which the sensor 141 is mounted.

[0163] In this case, the sensor 141 may be an infrared temperature sensor to measure the surface temperature of the container 10 in a non-contact manner, and while the sensor 141 is fixed to the mounting member 142, it may measure the surface temperature of the container 10 disposed in the heating space 121.

[0164] In addition, the heating blocks 122a, 122b may include placement holes 129a, 129b that are formed in a shape corresponding to the sensor 141 such that the sensor 141 may enter the heating space 121.

[0165] That is, the placement holes 129a, 129b may be formed to pass through the first heating block 122a and the second heating block 122b, respectively, and the placement holes 129a, 129b may be formed by joining a portion 129a that is formed in the first heating block 122a and a portion 129b that is formed in the second heating block 122b.

[0166] Accordingly, when the thawing part 120 is located at the heating position, the sensor 141 does not come into contact with the container 10 disposed in the heating space 121 through the placement holes 129a, 129b, and may measure the surface temperature of the container 10 at a location very close to the container 10.

[0167] Moreover, the temperature information measured by the sensor 141 may be used as information for detecting whether the container 10 is disposed in the heating space 121.

[0168] In the above description, an infrared temperature sensor is exemplified as the sensor 141, but the present invention is not limited thereto, and various known sensors may all be employed, and depending on the type of sensor employed, the information of the container 10 measured may vary.

[0169] Meanwhile, when the motor 131 is driven, the mounting member 142 may be provided to move in forward and backward directions in association with the operation of the power transmission member.

[0170] That is, when the first heating block 122a and the second heating block 122b are changed from the standby position to the heating position based on the state in which the container 10 is disposed in the heating space 121, the mounting member 142 may move in a direction closer to the container 10, and when the first heating block 122a and the second heating block 122b are changed from the heating position to the standby position, the mounting member 142 may move in a direction of moving away from the container 10.

[0171] To this end, as illustrated in FIGS. 6, 9 to 12 and 22, the sensing part 140 may include a roller member 143 which is rotatably coupled to the mounting member 142, and a contact member 144 which is fixedly coupled to the first heat insulating block 124a, protrudes a certain length in a direction parallel to the moving direction of the first insulation block 124a and is formed with a contact surface 145 with which the roller member 143 comes into contact, and the contact surface 145 may be formed as a flat cam.

[0172] In addition, as illustrated in FIGS. 9 and 10, the sensing part 140 may further include an elastic member 146 for pressing the mounting member 142 toward the heating space 121, and a fixture 147 which is coupled to the pedestal 125 so as to support an end of the elastic member 146.

[0173] In this case, as illustrated in FIGS. 6 and 22, the pedestal 125 may include a coupling groove 125b which is formed to be drawn from one surface to a certain depth such that a portion of the mounting member 142 can be accommodated, and a moving path 125c of a long hole which is formed through the coupling groove 125b such that the roller member 143 protruding from mounting member 142 can pass through, and the fixture 147 may be coupled to the pedestal 125 so as to cover a portion of the mounting member 142 that is inserted into the coupling groove 125b.

[0174] Accordingly, the mounting member 142 may be pressed toward the contact member 144 through the elastic force provided from the elastic member 146 in a state where a portion thereof is accommodated in the coupling groove 125b, and the roller member 143 may maintain a state of being in contact with the contact surface 145 of the contact member 144, and the roller member 143 may be rotated while one side thereof is in contact with the contact surface 145.

[0175] As a result, as described above, when the first guide block 134a to which the first heat insulating block 124a is fixed is slidably moved along the guide rail 135, the contact member 144 which is fixed to the first heat insulating block 124a may slidably move along the guide rail 135 together with the first insulation block 124a, and in the contact

surface 145, the position of a portion in contact with the roller member 143 may be changed.

[0176] That is, as illustrated in the enlarged views of FIGS. 6 and 22, the contact surface 145 may include a first portion 145a, a second portion 145b and a third portion 145c, and the first portion 145a and the third portion 145c may be connected to each other via the second portion 145b. In this case, the first portion 145a and the third portion 145c may be formed stepwise from each other, and the third portion 145c may be formed to protrude toward the roller member 43 relatively compared to the first portion 145a.

[0177] Accordingly, when the contact member 144 which is fixedly installed on the first heat insulating block 124a is slidably moved along the guide rail 135 together with the first heat insulating block 124a, as illustrated in FIGS. 9 and 10, a portion of the roller member 143 which is in contact with the contact surface 145 may be changed from the first portion 145a to the third portion 145c or from the third portion 145c to the first portion 145a.

[0178] As a result, as illustrated in FIGS. 11 and 12, as the mounting member 142 moves a certain distance (L) in the front and rear directions along the moving path 125c within the coupling groove 125b, it may move in a direction closer to the container 10 or move in a direction away from the container 10 based on the state in which the container 10 is disposed in the heating space 121.

[0179] Accordingly, as illustrated in FIG. 1, even if the container 10 includes a flange part 16 protruding from the container main body 12, the user may easily dispose a container 10 on the pedestal 125 or easily remove a container 10 from the pedestal 125 in a state where the first heating block 122a and the second heating block 122b are located at a standby position without being interfered by the sensor 141.

[0180] The control part 150 may control overall driving of the cell thawing machines 100, 200 according to one embodiment of the present invention.

[0181] As illustrated in FIG. 3, the control part 150 may include a circuit board 151 and a chipset 152 such as an MCU that is mounted on the circuit board 151, and the control part 150 may control all operations of the thawing part 120, the driving part 130, the sensing part 140, the display 118, the manipulation part 117 and the position detection means described above.

[0182] In this case, when heating the container 10 accommodated in the heating space 121 at the heating position, the control part 150 may control the driving of the driving part 130 so as to heat the container while the first heating block 122a and the second heating block 122b are in contact with each other, but it may control the driving of the driving part 130 so as to heat the container 10 while the first heating block 122a and the second heating block 122b do not come into contact with each other.

[0183] That is, the control part 150 may set the heating position such that a predetermined gap is formed in the remaining portion except for portions where the opposing surfaces 127a, 127b for forming the heating space 121 are formed among the surfaces of the first heating block 122a and the second heating block 122b facing each other.

[0184] Through this, the cell thawing machines 100, 200 according to one embodiment of the present invention may prevent a load that may occur in the motor 131 in order to maintain contact between the first heating block 122a and the second heating block 122b at the heating position.

[0185] Additionally, in the process of thawing the biological material contained in the container 10 at the heating position, the cell thawing machines 100, 200 according to one embodiment of the present invention may discharge water vapor or moisture generated from the surface of the container 10 to the outside through the gap. Through this, the biological material contained in the container 10 may be thawed more smoothly.

[0186] Moreover, after preheating the heating blocks 122a, 122b to a predetermined temperature through driving of the heaters 123a, 123b, the control part 150 may start thawing the biological material contained in the container 10.

[0187] As described above, the control part 150 may maintain the temperatures of the heating blocks 122a, 122b to be constant through PID control, and when the heating blocks 122a, 122b are provided in plurality, the control part 150 may individually control each of the heating blocks 122a, 122b.

[0188] Herein, the preheating temperature of the heating blocks 122a, 122b may be the same as the thawing temperature for thawing the biological material contained in the container 10 or may be a relatively higher temperature than the thawing temperature.

[0189] In addition, the control part 150 may maintain the temperatures of the heating blocks 122a, 122b to be constant while the container 10 which is introduced into the heating space 121 is completely thawed and the heating blocks 122a, 122b are changed to the standby position.

[0190] Through this, the cell thawing machines 100, 200 according to one embodiment of the present invention may be changed between the heating position and the standby position while the heating blocks 122a, 122b are continuously maintained at a constant temperature.

[0191] Accordingly, when the cell thawing machines 100, 200 according to one embodiment of the present invention are used, the user may sequentially introduce and remove a plurality of containers 10 into the heating space 121 to perform thawing, thereby minimizing the waiting time increase work productivity.

[0192] Meanwhile, the cell thawing machine 200 according to one embodiment of the present invention may conveniently perform qualification evaluation in order to verify the operating temperature of the heating block.

[0193] To this end, the cell thawing machine 200 according to one embodiment of the present invention may further include a sensor insertion hole 180, and the sensor insertion hole 180 may be formed to be drawn at a certain depth from one surface of the heating blocks 122a, 122b.

[0194] The sensor insertion hole 180 may be a space into which a calibration sensor is inserted during calibration in order to check whether the heating blocks 122a, 122b are normally operating.

[0195] For example, the calibration sensor (not illustrated) may be a bar-shaped temperature sensor having a predetermined length, and a partial length of the calibration sensor may be inserted into the sensor insertion hole 180.

[0196] Accordingly, since the checker may easily measure the temperatures of the heating blocks 122a, 122b through the calibration sensor inserted into the sensor insertion hole 180, it is possible to check whether the cell thawing machines 100, 200 according to one embodiment of the present invention are normally operating.

[0197] Although the sensor insertion hole 180 may be provided as one, when the heating blocks 122a, 122b include the above-described first heating block 122a and second heating block 122b, it may be provided in plurality so as to be respectively formed in the first heating block 122a and the second heating block 122b.

[0198] In this case, the sensor insertion hole 180 may be formed on a side surface of the heating blocks 122a, 122b, but as illustrated in FIG. 18, the sensor insertion hole 180 may be formed on the heating blocks 122a, 122b to be drawn in at a certain depth from the upper surface to the lower portion of the heating block 122a, 122b.

[0199] Accordingly, when the upper cover 114 on which the inlet 115 is formed is separated from the housing 110, the sensor insertion holes 180 formed on the upper surfaces of the heating blocks 122a, 122b may be exposed to the outside.

[0200] As a result, even if only the upper cover 114 is separated from the housing 110 without the need to separate the entire housing in the cell thawing machines 100, 200 according to one embodiment of the present invention, the sensor insertion hole 180 for calibration may be exposed to the outside.

[0201] Additionally, in the cell thawing machine 200 according to one embodiment of the present invention, since the sensor insertion hole 180 is formed to be drawn at a certain depth from the upper surface to the lower portion of the heating block 122a, 122b, the calibration sensor which is inserted into the sensor insertion hole 180 may maintain a state of being inserted upright into the sensor insertion hole 180 even without a separate fixing means.

[0202] Through this, after separating the upper cover 114, the checker may insert a partial length of the calibration sensor into the sensor insertion hole 180 formed on the upper surface of the heating block 122a, 122b, and then, it is possible to simply and accurately measure the operating temperatures of the heating block 122a, 122b.

[0203] In this case, the sensor insertion hole 180 may be formed to be located directly above the temperature sensors 128a, 128b that are embedded in the heating blocks 122a, 122b.

[0204] For example, as illustrated in FIG. 19, the sensor insertion hole 180 may be formed in the heating blocks 122a, 122b such that a lower end, which is a sealed end, is located directly above the temperature sensors 128a, 128b, and the lower end of the sensor insertion hole 180 may be formed on the heating block 122a, 122b to have a gap of 1 mm to 5 mm from the temperature sensor 128a, 128b.

[0205] Accordingly, during calibration, the temperatures of the heating blocks 122a, 122b measured by the calibration sensor inserted into the sensor insertion hole 180 may be similar to the temperatures of the heating blocks 122a, 122b measured by the temperature sensors 128a, 128b, when the cell thawing machines 100, 200 according to one embodiment of the present invention operate.

[0206] As a result, when calibration of the cell thawing machine 200 according to one embodiment of the present invention is performed by using the sensor insertion hole 180, the temperatures of the heating blocks 122a, 122b measured through the calibration sensor are similar to the temperatures of the heating blocks 122a, 122b measured by the temperature sensors 128a, 128b during normal operation, and thus, the calibration result may secure high reliability.

[0207] Hereinafter, the method for operating the above-described cell thawing machines 100, 200 will be described with reference to FIGS. 13 to 17 and 25 to 30.

[0208] First of all, as a preparation step, a cover 116 for covering the inlet 115 is removed, and power is supplied to the cell thawing machines 100, 200.

[0209] When power is applied to the cell thawing machines 100, 200, the control part 150 may drive the driving part 130 to change the thawing part 120 to a standby position.

[0210] That is, as illustrated in FIGS. 13 and 25, the control part 150 may drive the motor 131 to raise the moving member 136. Accordingly, the first heating block 122a and the second heating block 122b may be slid and moved away from each other, and may be changed to a standby position of being spaced apart from each other at a predetermined interval.

[0211] If the first heating block 122a and the second heating block 122b are located in the standby position, the preparation step of changing the thawing part 120 to the standby position when power is applied may be omitted.

[0212] Next, as a first step (S1), the control part 150 operates the first heater 123a and the second heater 123b to preheat the first heating block 122a and the second heating block 122b to a predetermined temperature.

[0213] For example, the preheating temperature of the first heating block 122a and the second heating block 122b may be equal to or relatively higher than the thawing temperature for thawing the biological material contained in the container 10.

[0214] In this case, the preheating of the first heating block 122a and the second heating block 122b may be performed in a state where surfaces of the first heating block 122a and the second heating block 122b facing each other are in contact with each other.

[0215] That is, as illustrated in FIGS. 14 and 26, the control part 150 may lower the moving member 136 by driving the motor 131. Accordingly, the first heating block 122a and the second heating block 122b may slid and moved in a direction closer to each other in the standby position, respectively, and they may be changed to a state where surfaces of the first heating block 122a and the second heating block 122b facing each other are in contact with each other.

[0216] In this state, the control part 150 may control the driving of the motor 131 such that the contact state of the first heating block 122a and the second heating block 122b may be maintained until the preheating of the first heating block 122a and the second heating block 122b is finished.

[0217] Accordingly, while the first heating block 122a and the second heating block 122b are in contact with each other, the first heating block 122a and the second heating block 122b may be simultaneously heated through a first heater 123a and a second heater 123b that are respectively placed on both sides, and thus, the first heating block 122a and the second heating block 122b may be quickly heated to a predetermined temperature through heat transferred from the first heater 123a and the second heater 123b.

[0218] Thereafter, when the preheating of the first heating block 122a and the second heating block 122b is completed, the control part 150 may output a message indicating that the preheating is completed to the display 118, and the control part 150 may slide and move the first heating block 122a and the second heating block 122b by driving the motor 131.

Through this, as illustrated in FIG. 15, the first heating block 122a and the second heating block 122b may be changed to a standby position of being spaced apart from each other at a predetermined interval.

[0219] In this way, when the preheating of the first heating block 122a and the second heating block 122b is completed, the user may check the set thawing time through the display 118, and if the set thawing time needs to be changed, the user may manipulate the manipulation part 117 to change the set thawing time to an appropriate time.

[0220] Next, as illustrated in FIGS. 15 and 27, in a state where the first heating block 122a and the second heating block 122b are located in the standby position, the user may dispose a container 10 that needs to be thawed between the first heating block 122a and the second heating block 122b that are disposed in the standby position. In this case, the container 10 may be disposed such that a flange part 16 is inserted into the seating groove 125a while the lower surface is seated on one surface of the protruding member 125d.

[0221] Thereafter, the user may input a thawing start signal through the manipulation part 117 in a state where the container 10 that needs to be thawed is placed between the first heating block 122a and the second heating block 122b that are disposed in the standby position.

[0222] Accordingly, the control part 150 may heat the container 10 so as to thaw the biological material contained in the container 10 as a second step (S2).

[0223] That is, the control part 150 may lower the moving member 136 by driving the motor 131 such that the first heating block 122a and the second heating block 122b can be moved in a direction closer to each other.

[0224] Accordingly, as illustrated in FIGS. 16 and 28, the first heating block 122a and the second heating block 122b may be changed from a standby position to a heating position for forming a heating space 121 for accommodating and heating the container 10, and the circumferential surface of the container 10 may be surrounded by the first heating block 122a and the second heating block 122b in a state where the container 10 is disposed in the heating space 121.

[0225] In addition, as described above, the sensor 141 may be connected to the linear movement of the first heating block 122a and the second heating block 122b to move toward the placement holes 129a, 129b that are respectively formed on the first heating block 122a and the second heating block 122b such that it is possible to detect the state of the container accommodated in the heating space 121.

[0226] Through this, the container 10 may be heated by the thawing time set by the user through the heat transferred from the first heating block 122a and the second heating block 122b, and through the sensor 141, it is possible to measure the state of the container 10 in real time.

[0227] In this case, the control part 150 may output a message indicating that it is thawing to the display 118, and based on the temperature information transmitted from the first temperature sensor 128a and the second temperature sensor 128b, the temperatures of the first heating block 122a and the second heating block 122b may be maintained to be constant by controlling the operation of the first heater 123a and the second heater 123b, and the state information about the container 10 detected through the sensor 141 may be output to the display 118 through driving of the control part 150.

[0228] In this case, as described above, while the container 10 disposed in the heating space 121 is not in contact with

the first heating block **122a** and the second heating block **122b**, it may be heated by the heat transferred from the first heating block **122a** and the second heating block **122b** in a non-contact manner.

[0229] That is, while the container **10** is inserted into the heating space **121**, the circumferential surface of the container **10** may be spaced apart by a predetermined interval from the opposing surface **127a** of the first heating block **122a** and the opposing surface **127b** of the second heating block **122b** forming the heating space **121**.

[0230] Through this, a gap (d) may be formed between the pair of opposing surfaces **127a**, **127b** and the outer surface of the container **10** in a state where the container **10** is disposed in the heating space **121**.

[0231] Accordingly, the heat stored in the first heating block **122a** and the second heating block **122b** may be transferred to the relatively low-temperature container **10** through convection and/or radiation instead of conduction.

[0232] As a result, since the circumferential surface of the container **10** may be heated through convective heat and/or radiant heat, the circumferential surface of the container **10** may be uniformly heated by convective heat and/or radiant heat transferred from the heating block **122a**, **122b**.

[0233] Additionally, in the second step (S2), the control part **150** may control the driving of the motor **131** so as to heat the container **10** in a state where the first heating block **122a** and the second heating block **122b** are in contact with each other, but it may control the driving of the motor **131** so as to heat the container **10** in a state where the first heating block **122a** and the second heating block **122b** do not contact each other.

[0234] That is, the control part **150** may set the heating position such that a predetermined gap is formed in the remaining portion except for portions where the opposing surfaces **127a**, **127b** for forming the heating space **121** are formed among the surfaces of the first heating block **122a** and the second heating block **122b** facing each other.

[0235] Through this, the cell thawing machines **100**, **200** according to one embodiment of the present invention may prevent a load that may occur in the motor in order to maintain the state where the first heating block **122a** and the second heating block **122b** are in contact with each other in the heating position, and in the process of thawing the biological material contained in the container **10** at the heating position, it is possible to discharge water vapor or moisture generated from the surface of the container **10** to the outside through the gap, and thus, it is possible to thaw the biological material more smoothly.

[0236] Next, when the thawing time set by the user elapses, the control part **150** may output a message indicating completion to the display **118**, and as a third step (S3), the control part **150** may drive the motor **131** to change the first heating block **122a** and the second heating block **122b** to the standby position.

[0237] Accordingly, as illustrated in FIGS. **17** and **29**, the user may remove the container **10** disposed between the first heating block **122a** and the second heating block **122b** while the first heating block **122a** and the second heating block **122a** are located in the standby position.

[0238] In this case, the control part **150** may control the driving of the first heater **123a** and the second heater **123b** such that the temperatures of the first heating block **122a** and the second heating block **122b** are continuously maintained to be constant.

[0239] Accordingly, the user may sequentially thaw a plurality of containers **10** by sequentially repeating the first step (S1) and the second step (S2).

[0240] Although one exemplary embodiment of the present invention has been described above, the spirit of the present invention is not limited to the exemplary embodiments presented herein, and those skilled in the art who understand the spirit of the present invention may easily suggest other exemplary embodiments by changing, modifying, deleting or adding components within the scope of the same spirit, but this will also fall within the scope of the present invention.

What is claimed is:

1. A cell thawing machine, comprising:

a thawing part comprising a heating block, wherein the heating block comprises a first heating block and a second heating block that form a heating space for heating a container in which a predetermined amount of biological material including cells is stored, a heater, wherein the heater is installed in the heating block to provide heat to the heating block, a heat insulating block, wherein the heat insulating block is coupled to the heating block to surround the heater, and a pedestal configured to support a lower portion of the container in the heating space;

a driving part for providing a driving force that linearly moves each of the first heating block and the second heating block in left and right directions;

a sensing part comprising a sensor for detecting the state of the container disposed in the heating space, and a mounting member on which the sensor is mounted and, wherein the mounting member moves in forward and backward directions in connection with the operation of the driving part; and

a control part for controlling the operations of the thawing part, the driving part and the sensing part.

2. The cell thawing machine according to claim 1, wherein the container is accommodated in the heating space and is heated by heat transferred from the heating block in a non-contact manner without contacting the heating block.

3. The cell thawing machine according to claim 1, wherein the heating block is made of a thermally conductive material.

4. The cell thawing machine according to claim 1, wherein the heating block comprises an arrangement groove that is formed to be drawn inward on one surface, the heater is inserted into the arrangement groove, and the heat insulating block is coupled to the heating block to cover the arrangement groove.

5. The cell thawing machine according to claim 1, wherein the heating space is formed through opposing surfaces that are formed to be each drawn inward to have a shape corresponding to the circumferential surface of the container on surfaces facing each other in the first heating block and the second heating block.

6. The cell thawing machine according to claim 1, wherein the pedestal comprises a seating groove that is formed on one surface facing the heating space such that a lower edge of the container can be inserted therein.

7. The cell thawing machine according to claim 1, wherein the thawing part comprises a temperature sensor that is installed on the heating block to measure the temperature of the heating block.

8. The cell thawing machine according to claim 7, wherein the cell thawing machine further comprises a sensor insertion hole that is formed to be drawn at a certain depth from an upper surface of the heating block to a lower portion such that a calibration sensor for measuring the temperature of the heating block can be inserted therein, and

wherein the sensor insertion hole is formed to be located directly above the temperature sensor.

9. The cell thawing machine according to claim 1, wherein the driving part comprises a motor for providing a driving force, a rotating member, wherein the rotating member is axially coupled to a rotating shaft of the motor, and a power transmission member for interconnecting the rotating member and the thawing part such that the first heating block and the second heating block can be moved linearly in the left and right directions, respectively, through the driving force of the motor.

10. The cell thawing machine according to claim 9, wherein the power transmission member comprises a guide block, wherein the guide block is fixedly coupled to the heat insulating block, a guide rail, wherein the guide rail guides the linear movement of the guide block, a moving member, wherein the moving member moves up and down along the rotating member through the driving force of the motor, and a link member for linking the guide block and the moving member to each other.

11. The cell thawing machine according to claim 1, wherein the sensing part comprises a roller member, wherein the roller member is rotatably coupled to the mounting member, and a contact member, wherein the contact member is fixedly coupled to the heat insulating block and protrudes a certain length in a direction parallel to the moving direction of the heat insulating block to form a contact surface with which the roller member comes into contact, and wherein the contact surface is formed by a flat cam.

12. The cell thawing machine according to claim 11, wherein the sensing part further comprises an elastic member, wherein the elastic member presses the mounting member toward the heating space, and a fixture, wherein the fixture is coupled to the pedestal to support an end of the elastic member.

13. The cell thawing machine according to claim 11, wherein the pedestal comprises a movement path of a long hole, wherein the long hole is formed to penetrate such that the roller member protruding from the mounting member can pass through.

14. The cell thawing machine according to claim 1, wherein the cell thawing machine further comprises a limit switch for detecting the position of the heating block through contact with the heat insulating block.

15. The cell thawing machine according to claim 1, wherein the cell thawing machine further comprises a non-contact position detection sensor for detecting the position of the heating block.

16. The cell thawing machine according to claim 1, wherein the cell thawing machine comprises a housing having an inlet that is formed through a position corresponding to the heating space.

17. The cell thawing machine according to claim 16, wherein the cell thawing machine further comprises a sensor insertion hole, wherein the sensor insertion hole is formed to be drawn at a certain depth from an upper surface of the heating block to a lower portion such that a calibration sensor for measuring the temperature of the heating block can be inserted therein,

wherein the housing comprises a box-shaped main body and an upper cover, wherein the upper cover is detachably coupled to the main body so as to cover an upper portion of the main body,

wherein the inlet is formed on the upper cover to be located in a position corresponding to the heating space, and

wherein the sensor insertion hole is exposed to the outside when the upper cover and the main body are separated.

18. The cell thawing machine according to claim 1, wherein when heating a container accommodated in the heating space, the control part controls the driving of the driving part to heat the container in a state where the first heating block and the second heating block are not in contact with each other.

19. The cell thawing machine according to claim 1, wherein the control part individually controls the temperatures of the first heating block and the second heating block.

20. A method for operating a cell thawing machine comprising a heating block comprising a first heating block and a second heating block which form a heating space for accommodating and heating a container in which a predetermined amount of biological material including cells is stored through linear movement by a driving force of a motor, and heat the container accommodated in the heating space through heat provided from a heater; and a sensor for changing a position in connection with the linear movement of the heating block and detecting the state of the container disposed in the heating space, the method comprising:

- a first step of preheating the first heating block and the second heating block to a predetermined temperature by driving the heater while one surface of the first heating block and one surface of the second heating block facing each other are in contact with each other;
- a second step of heating the container disposed in the heating space to thaw the biological material while the first heating block and the second heating block are changed to a heating position forming the heating space; and
- a third step of changing the first heating block and the second heating block to a standby position by moving the same in a direction of moving away from the heating position such that the container disposed in the heating space can be removed,

wherein in the second step, the container disposed in the heating space is heated by heat transferred from the first heating block and the second heating block in a non-contact manner without contacting the first heating block and the second heating block.
