### SECURELY RECORDING AND RETRIEVING ENCRYPTED VIDEO CONFERENCES

---

#### Abstract

One disclosed example method includes obtaining a meeting cryptographic key; transmitting, from a client device to a video conference provider, a request to initiate an encrypted video conference, the encrypted video conference including a plurality of participants; distributing the meeting cryptographic key to each participant of the plurality of participants; obtaining a public cryptographic key of a key pair, the key pair including the public cryptographic key and a private cryptographic key; encrypting the meeting cryptographic key using the public cryptographic key; transmitting, from the client device to the video conference provider, a request to record the video conference; encrypting audio and video from a microphone and image sensor of the client device using the meeting cryptographic key; transmitting the encrypted audio and video to the video conference provider; and providing the encrypted meeting cryptographic key to the video conference provider.

## Background/Summary

CROSS-REFERENCE [0001] This application is a continuation of U.S. patent application Ser. No. 18/124,640, filed Mar. 22, 2023, titled “Securely Recording and Retrieving Encrypted Video Conferences,” which is a continuation of U.S. patent application Ser. No. 17/162,382, now U.S. Pat. No. 11,637,818, filed Jan. 29, 2021, titled “Securely Recording and Retrieving Encrypted Video Conferences,” the entireties of both of which are hereby incorporated by reference.

### FIELD

[0002] The present application generally relates to hosting or participating in video conferences and more particularly relates to systems and methods for recording encrypted video conferences.

### BACKGROUND

[0003] Videoconferencing has become a common way for people to meet as a group, but without being at the same physical location. Participants can be invited to a video conference meeting, join from their personal computers or telephones, and are able to see and hear each other and converse largely as they would during an in-person group meeting or event. The advent of user-friendly video conferencing software has enabled teams to work collaboratively despite being dispersed around the country or the world. It has also enabled families and friends to engage with each other in more meaningful ways, despite being physically distant from each other.

### SUMMARY

[0004] Various examples are described for systems and methods for securely recording and retrieving encrypted video conferences. One example method includes obtaining a meeting cryptographic key; transmitting, from a client device to a video conference provider, a request to initiate an encrypted video conference, the encrypted video conference including a plurality of participants; distributing the meeting cryptographic key to each participant of the plurality of participants; obtaining a public cryptographic key of a key pair, the key pair including the public cryptographic key and a private cryptographic key; encrypting the meeting cryptographic key using the public cryptographic key; transmitting, from the client device to the video conference provider, a request to record the video conference; encrypting audio and video from a microphone and image sensor of the client device using the meeting cryptographic key; transmitting the encrypted audio and video to the video conference provider; and providing the encrypted meeting cryptographic key to the video conference provider.

[0005] Another example method includes initiating, by a video conference provider, an encrypted video conference; receiving and storing, by the video conference provider, encrypted streams of audio and video from a plurality of participants in the video conference, the encrypted audio and video encrypted by the respective participants using a meeting cryptographic key, wherein the video conference provider does not have access to the meeting cryptographic key; providing multiplexed encrypted streams of audio and video to the participants; receiving and storing an

encrypted meeting cryptographic key; associating the encrypted audio and video with the encrypted meeting cryptographic key; receiving, by the video conference provider after the videoconference has ended, a request for the stored encrypted audio and video and the encrypted meeting cryptographic key; providing, in response to the request, the stored encrypted audio and video and the encrypted meeting cryptographic key.

[0006] One example system includes a non-transitory computer-readable medium; a communications interface; a microphone; an image sensor; and a processor communicatively coupled to the non-transitory computer-readable medium, the communications interface, the microphone, and the image sensor the processor configured to execute processor-executable instructions stored in the non-transitory computer-readable medium to receive audio from the microphone and video from the image sensor; obtain a meeting cryptographic key; transmit, to a video conference provider, a request to initiate an encrypted video conference, the encrypted video conference including a plurality of participants; distribute the meeting cryptographic key to each participant of the plurality of participants; obtain a public cryptographic key of a key pair, the key pair including the public cryptographic key and a private cryptographic key; encrypt the meeting cryptographic key using the public cryptographic key; transmit, to the video conference provider, a request to record the video conference; encrypt audio and video from a microphone and image sensor of the client device using the meeting cryptographic key; transmit the encrypted audio and video to the video conference provider; and transmit the encrypted meeting cryptographic key to the video conference provider.

[0007] Another example system includes a non-transitory computer-readable medium; a communications interface; and a processor communicatively coupled to the non-transitory computer-readable medium and the communications interface, the processor configured to execute processor-executable instructions stored in the non-transitory computer-readable medium to initiate an encrypted video conference; receive and store encrypted streams of audio and video from a plurality of participants of the video conference, the encrypted audio and video encrypted by the respective participants using an encrypted meeting cryptographic key, wherein the processor does not have access to the meeting cryptographic key; multiplex the encrypted streams of audio and video and provide multiplexed encrypted streams of audio and video to the participants; receive and store an encrypted meeting cryptographic key; associate the encrypted audio and video with the encrypted meeting cryptographic key; terminate the encrypted video conference; receive a request for the stored encrypted audio and video and the encrypted meeting cryptographic key; provide, in response to the request, the stored encrypted audio and video and the encrypted meeting cryptographic key.

[0008] One example non-transitory computer-readable medium includes processor-executable instructions configured to cause a processor to receive audio from a microphone and video from an image sensor; obtain a meeting cryptographic key; transmit, to a video conference provider, a request to initiate an encrypted video conference, the encrypted video conference including a plurality of participants; distribute the meeting cryptographic key to each participant of the plurality of participants; obtain a public cryptographic key of a key pair, the key pair including the public cryptographic key and a private cryptographic key; encrypt the meeting cryptographic key using the public cryptographic key; transmit, to the video conference provider, a request to record the video conference; encrypt audio and video from a microphone and image sensor of the client device using the meeting cryptographic key; transmit the encrypted audio and video to the video conference provider; and transmit the encrypted meeting cryptographic key to the video conference provider.

[0009] Another example non-transitory computer-readable medium includes processor-executable instructions configured to cause a processor to initiate an encrypted video conference; receive and store encrypted streams of audio and video from a plurality of participants of the video conference, the encrypted audio and video encrypted by the respective participants using an encrypted meeting

cryptographic key, wherein the processor does not have access to the meeting cryptographic key; multiplex the encrypted streams of audio and video and provide multiplexed encrypted streams of audio and video to the participants; receive and store an encrypted meeting cryptographic key; associate the encrypted audio and video with the encrypted meeting cryptographic key; terminate the encrypted video conference; receive a request for the stored encrypted audio and video and the encrypted meeting cryptographic key; provide, in response to the request, the stored encrypted audio and video and the encrypted meeting cryptographic key.

[0010] These illustrative examples are mentioned not to limit or define the scope of this disclosure, but rather to provide examples to aid understanding thereof. Illustrative examples are discussed in the Detailed Description, which provides further description. Advantages offered by various examples may be further understood by examining this specification.

---

## Description

### BRIEF DESCRIPTION OF THE DRAWINGS

[0011] The accompanying drawings, which are incorporated into and constitute a part of this specification, illustrate one or more certain examples and, together with the description of the example, serve to explain the principles and implementations of the certain examples.

[0012] FIGS. 1-4 show example systems for securely recording and retrieving encrypted video conferences;

[0013] FIGS. 5-7 show example methods for securely recording and retrieving encrypted video conferences;

[0014] FIG. 8 shows an example system for securely recording and retrieving encrypted video conferences;

[0015] FIGS. 9-10 show example methods for securely recording and retrieving encrypted video conferences; and

[0016] FIG. 11 shows an example computing device suitable for use with any system or method for securely recording and retrieving encrypted video conferences according to this disclosure.

### DETAILED DESCRIPTION

[0017] Examples are described herein in the context of systems and methods for securely recording and retrieving encrypted video conferences. Those of ordinary skill in the art will realize that the following description is illustrative only and is not intended to be in any way limiting. Reference will now be made in detail to implementations of examples as illustrated in the accompanying drawings. The same reference indicators will be used throughout the drawings and the following description to refer to the same or like items.

[0018] In the interest of clarity, not all of the routine features of the examples described herein are shown and described. It will, of course, be appreciated that in the development of any such actual implementation, numerous implementation-specific decisions must be made in order to achieve the developer's specific goals, such as compliance with application- and business-related constraints, and that these specific goals will vary from one implementation to another and from one developer to another.

[0019] People participate in video conferences for a wide variety of reasons, such as to keep in touch with family, conduct business, or manage groups or organizations. In some cases, participants in a video conference may wish to keep the contents of the video conference confidential and only available to certain authorized personnel. This can be done by encrypting audio and video that is streamed between participants to a video conference, which may prevent potential eavesdroppers from accessing the streamed audio and video. Without the necessary decryption information, accessing the encrypted audio and video can be prohibitively computationally difficult. However, in some scenarios, audio and video data may be decrypted

during the course of an encrypted video conference.

[0020] For example, some video conference providers offer the option of recording a video conference. In some examples, the video conference provider itself, being the nexus through which the audio and video traverses, will record the meeting and provide access to the recorded meeting to one or more of the participants. However, to perform this functionality, the video conference provider needs to decrypt the audio and video for recording, even if the recorded audio and video is subsequently encrypted. Thus, the video conference provider has access to the encrypted audio and video of the video conference. Such a scenario may be undesirable for any number of reasons. For example, the video conference provider's servers may be "untrusted" by the participants, meaning the provenance and identity of the servers may not be verifiable by the participants or may otherwise be suspect. In some cases, the audio or video may include confidential information that may not be shared with the video conference provider, e.g., by law or regulation. Further, the participants themselves may simply not want the video conference provider to have access to the content of the video conference.

[0021] To provide security for the video conference, the participants may use an option to encrypt audio and video data between the participants and distribute cryptographic information amongst the participants without sharing that cryptographic information with the video conference provider. Thus, all of the participants are able to receive encrypted audio and video and decrypt it, but while the video conference provider continues to receive the encrypted video and audio and distribute it to the participants, it is unable to decrypt it. However, this presents a problem for participants that would like to have the meeting recorded because, while the video conference provider can store the encrypted data, it does not have the keys used to encrypt and decrypt the audio and video. Further, the keys used during the video conference are discarded either during the video conference (due to rotating to new encryption keys) or when the video conference ends.

[0022] To enable the video conference provider to record an encrypted video conference and allow one or more participants to later retrieve the recorded video conference and access it, the host requests that the video conference initiate an encrypted video conference and the host generates a meeting cryptographic key, e.g., a symmetric encryption key. In addition, the host obtains, e.g., by generating an asymmetric cryptographic key pair, a public key of a cryptographic key pair, which it uses to encrypt the meeting cryptographic key.

[0023] During the video conference, the participants employ the meeting cryptographic key to encrypt the audio and video, which is received and stored by the video conference provider as well as distributed to the various participants to enable them to participate in the video conference. In addition, the host provides the encrypted meeting cryptographic key to the video conference provider, which associates it with the encrypted audio and video.

[0024] During the video conference, the host may rotate through multiple meeting cryptographic keys, thereby causing the video conference to be encrypted using different keys over time. For each key rotation, the new meeting cryptographic key is encrypted (using the previously obtained public key) and uploaded to the video conference provider, which associates it with the recorded encrypted video conference.

[0025] Once the meeting is over, the host (or other meeting participant) can subsequently retrieve the encrypted audio and video as well as the encrypted meeting cryptographic key(s) provided to the video conference provider. The host uses the private key corresponding to the public key used to encrypt the meeting cryptographic key (or keys, if multiple meeting cryptographic keys were used). It can then decrypt the audio and video using the decrypted meeting cryptographic key(s).

[0026] By using such a technique, the encrypted audio and video is secure while it is saved at the video conference provider. The decryption key is also stored with the video conference provider, however, because it is encrypted, it is inaccessible. Further, while the host in this example is described as generating the cryptographic key pair, the public key may instead be provided by a key management server, such as one hosted by a customer of the video conference provider. Thus,

the host may never have access to the private key needed to decrypt the video conference before it is provided to the video conference provider. Instead, the host may need to request decryption of the private key at a later time, which may require authentication to the key management service, thereby further ensuring the security of the audio and video from the video conference.

[0027] Using such techniques, hosts and participants in a video conference may enjoy privacy for their communications and ensure that access to a video conference recording is similarly restricted. As noted above, this can help comply with various privacy regulations or ensure that other attempts to access the encrypted recording must be mediated by the host (or corresponding entity, such as the host's employer).

[0028] This illustrative example is given to introduce the reader to the general subject matter discussed herein and the disclosure is not limited to this example. The following sections describe various additional non-limiting examples and examples of systems and methods for securely recording and retrieving encrypted video conferences.

[0029] Referring now to FIG. 1, FIG. 1 shows an example system **100** that provides videoconferencing functionality to various client devices. The system **100** includes a video conference provider **110** that is connected to multiple communication networks **120**, **130**, through which various client devices **140-180** can participate in video conferences hosted by the video conference provider **110**. For example, the video conference provider **120** can be located within a private network to provide video conferencing services to devices within the private network, or it can be connected to a public network, e.g., the internet, so it may be accessed by anyone. Some examples may even provide a hybrid model in which a video conference provider **120** may supply components to enable a private organization to host private internal video conferences or to connect its system to the video conference provider **120** over a public network.

[0030] The system optionally also includes one or more user identity providers, e.g., user identity provider **115**, which can provide user identity services to users of the client devices **140-160** and may authenticate user identities of one or more users to the video conference provider **110**. In this example, the user identity provider **115** is operated by a different entity than the video conference provider **110**, though in some examples, they may be the same entity.

[0031] Video conference provider **110** allows clients to create videoconference meetings (or “meetings”) and invite others to participate in those meetings as well as perform other related functionality, such as recording the meetings, generating transcripts from meeting audio, manage user functionality in the meetings, enable text messaging during the meetings, create and manage breakout rooms from the main meeting, etc. FIG. 2, described below, provides a more detailed description of the architecture and functionality of the video conference provider **110**.

[0032] Meetings in this example video conference provider **110** are provided in virtual “rooms” to which participants are connected. The room in this context is a construct provided by a server that provides a common point at which the various video and audio data is received before being multiplexed and provided to the various participants. While a “room” is the label for this concept in this disclosure, any suitable functionality that enables multiple participants to participate in a common videoconference may be used. Further, in some examples, and as alluded to above, a meeting may also have “breakout” rooms. Such breakout rooms may also be rooms that are associated with a “main” videoconference room. Thus, participants in the main videoconference room may exit the room into a breakout room, e.g., to discuss a particular topic, before returning to the main room. The breakout rooms in this example are discrete meetings that are associated with the meeting in the main room. However, to join a breakout room, a participant must first enter the main room. A room may have any number of associated breakout rooms according to various examples.

[0033] To create a meeting with the video conference provider **110**, a user may contact the video conference provider **110** using a client device **140-180** and select an option to create a new meeting. Such an option may be provided in a webpage accessed by a client device **140-160** or

client application executed by a client device **140-160**. For telephony devices, the user may be presented with an audio menu that they may navigate by pressing numeric buttons on their telephony device. To create the meeting, the video conference provider **110** may prompt the user for certain information, such as a date, time, and duration for the meeting, a number of participants, a type of encryption to use, whether the meeting is confidential or open to the public, etc. After receiving the various meeting settings, the video conference provider may create a record for the meeting and generate a meeting identifier and, in some examples, a corresponding meeting password or passcode (or other authentication information), all of which meeting information is provided to the meeting host.

[0034] After receiving the meeting information, the user may distribute the meeting information to one or more users to invite them to the meeting. To begin the meeting at the scheduled time (or immediately, if the meeting was set for an immediate start), the host provides the meeting identifier and, if applicable, corresponding authentication information (e.g., a password or passcode). The video conference system then initiates the meeting and may admit users to the meeting. Depending on the options set for the meeting, the users may be admitted immediately upon providing the appropriate meeting identifier (and authentication information, as appropriate), even if the host has not yet arrived, or the users may be presented with information indicating the that meeting has not yet started or the host may be required to specifically admit one or more of the users.

[0035] During the meeting, the participants may employ their client devices **140-180** to capture audio or video information and stream that information to the video conference provider **110**. They also receive audio or video information from the video conference provider **210**, which is displayed by the respective client device **140** to enable the various users to participate in the meeting.

[0036] At the end of the meeting, the host may select an option to terminate the meeting, or it may terminate automatically at a scheduled end time or after a predetermined duration. When the meeting terminates, the various participants are disconnected from the meeting and they will no longer receive audio or video streams for the meeting (and will stop transmitting audio or video streams). The video conference provider **110** may also invalidate the meeting information, such as the meeting identifier or password/passcode.

[0037] To provide such functionality, one or more client devices **140-180** may communicate with the video conference provider **110** using one or more communication networks, such as network **120** or the public switched telephone network (“PSTN”) **130**. The client devices **140-180** may be any suitable computing or communications device that have audio or video capability. For example, client devices **140-160** may be conventional computing devices, such as desktop or laptop computers having processors and computer-readable media, connected to the video conference provider **110** using the internet or other suitable computer network. Suitable networks include the internet, any local area network (“LAN”), metro area network (“MAN”), wide area network (“WAN”), cellular network (e.g., 3G, 4G, 4G LTE, 5G, etc.), or any combination of these. Other types of computing devices may be used instead or as well, such as tablets, smartphones, and dedicated video conferencing equipment. Each of these devices may provide both audio and video capabilities and may enable one or more users to participate in a video conference meeting hosted by the video conference provider **110**.

[0038] In addition to the computing devices discussed above, client devices **140-180** may also include one or more telephony devices, such as cellular telephones (e.g., cellular telephone **170**), internet protocol (“IP”) phones (e.g., telephone **180**), or conventional telephones. Such telephony devices may allow a user to make conventional telephone calls to other telephony devices using the PSTN, including the video conference provider **110**. It should be appreciated that certain computing devices may also provide telephony functionality and may operate as telephony devices. For example, smartphones typically provide cellular telephone capabilities and thus may operate as telephony devices in the example system **100** shown in FIG. **1**. In addition, conventional computing devices may execute software to enable telephony functionality, which may allow the user to make

and receive phone calls, e.g., using a headset and microphone. Such software may communicate with a PSTN gateway to route the call from a computer network to the PSTN. Thus, telephony devices encompass any devices that can making conventional telephone calls and is not limited solely to dedicated telephony devices like conventional telephones.

[0039] Referring again to client devices **140-160**, these devices **140-160** contact the video conference provider **110** using network **120** and may provide information to the video conference provider **110** to access functionality provided by the video conference provider **110**, such as access to create new meetings or join existing meetings. To do so, the client devices **140-160** may provide user identification information, meeting identifiers, meeting passwords or passcodes, etc. In examples that employ a user identity provider **115**, a client device, e.g., client devices **140-160**, may operate in conjunction with a user identity provider **115** to provide user identification information or other user information to the video conference provider **110**.

[0040] A user identity provider **115** may be any entity trusted by the video conference provider **110** that can help identify a user to the video conference provider **110**. For example, a trusted entity may be a server operated by a business or other organization and with whom the user has established their identity, such as an employer or trusted third-party. The user may sign into the user identity provider **115**, such as by providing a username and password, to access their identity at the user identity provider **115**. The identity, in this sense, is information established and maintained at the user identity provider **115** that can be used to identify a particular user, irrespective of the client device they may be using. An example of an identity may be an email account established at the user identity provider **110** by the user and secured by a password or additional security features, such as biometric authentication, two-factor authentication, etc. However, identities may be distinct from functionality such as email. For example, a health care provider may establish identities for its patients. And while such identities may have associated email accounts, the identity is distinct from those email accounts. Thus, a user's "identity" relates to a secure, verified set of information that is tied to a particular user and should be accessible only by that user. By accessing the identity, the associated user may then verify themselves to other computing devices or services, such as the video conference provider **110**.

[0041] When the user accesses the video conference provider **110** using a client device, the video conference provider **110** communicates with the user identity provider **115** using information provided by the user to verify the user's identity. For example, the user may provide a username or cryptographic signature associated with a user identity provider **115**. The user identity provider **115** then either confirms the user's identity or denies the request. Based on this response, the video conference provider **110** either provides or denies access to its services, respectively.

[0042] For telephony devices, e.g., client devices **170-180**, the user may place a telephone call to the video conference provider **110** to access video conference services. After the call is answered, the user may provide information regarding a video conference meeting, e.g., a meeting identifier ("ID"), a passcode or password, etc., to allow the telephony device to join the meeting and participate using audio devices of the telephony device, e.g., microphone(s) and speaker(s), even if video capabilities are not provided by the telephony device.

[0043] Because telephony devices typically have more limited functionality than conventional computing devices, they may be unable to provide certain information to the video conference provider **110**. For example, telephony devices may be unable to provide user identification information to identify the telephony device or the user to the video conference provider **110**. Thus, the video conference provider **110** may provide more limited functionality to such telephony devices. For example, the user may be permitted to join a meeting after providing meeting information, e.g., a meeting identifier and passcode, but they may be identified only as an anonymous participant in the meeting. This may restrict their ability to interact with the meetings in some examples, such as by limiting their ability to speak in the meeting, hear or view certain content shared during the meeting, or access other meeting functionality, such as joining breakout

rooms or engaging in text chat with other participants in the meeting.

[0044] It should be appreciated that users may choose to participate in meetings anonymously and decline to provide user identification information to the video conference provider **110**, even in cases where the user has an authenticated identity and employs a client device capable of identifying the user to the video conference provider **110**. The video conference provider **110** may determine whether to allow such anonymous users to use services provided by the video conference provider **110**. Anonymous users, regardless of the reason for anonymity, may be restricted as discussed above with respect to users employing telephony devices, and in some cases may be prevented from accessing certain meetings or other services, or may be entirely prevented from accessing the video conference provider.

[0045] Referring again to video conference provider **110**, in some examples, it may allow client devices **140-160** to encrypt their respective video and audio streams to help improve privacy in their meetings. Encryption may be provided between the client devices **140-160** and the video conference provider **110** or it may be provided in an end-to-end configuration where multimedia streams transmitted by the client devices **140-160** are not decrypted until they are received by another client device **140-160** participating in the meeting. Encryption may also be provided during only a portion of a communication, for example encryption may be used for otherwise unencrypted communications that cross international borders.

[0046] Client-to-server encryption may be used to secure the communications between the client devices **140-160** and the video conference provider **110**, while allowing the video conference provider **110** to access the decrypted multimedia streams to perform certain processing, such as recording the meeting for the participants or generating transcripts of the meeting for the participants. End-to-end encryption may be used to keep the meeting entirely private to the participants without any worry about a video conference provider **110** having access to the substance of the meeting. Any suitable encryption methodology may be employed, including key-pair encryption of the streams. For example, to provide end-to-end encryption, the meeting host's client device may obtain public keys for each of the other client devices participating in the meeting and securely exchange a set of keys to encrypt and decrypt multimedia content transmitted during the meeting. Thus the client devices **140-160** may securely communicate with each other during the meeting. Further, in some examples, certain types of encryption may be limited by the types of devices participating in the meeting. For example, telephony devices may lack the ability to encrypt and decrypt multimedia streams. Thus, while encrypting the multimedia streams may be desirable in many instances, it is not required as it may prevent some users from participating in a meeting.

[0047] By using the example system shown in FIG. **1**, users can create and participate in meetings using their respective client devices **140-180** via the video conference provider **110**. Further, such a system enables users to use a wide variety of different client devices **140-180** from traditional standards-based video conferencing hardware to dedicated video conferencing equipment to laptop or desktop computers to handheld devices to legacy telephony devices. etc.

[0048] Referring now to FIG. **2**, FIG. **2** shows an example system **200** in which a video conference provider **210** provides videoconferencing functionality to various client devices **220-250**. The client devices **220-250** include two conventional computing devices **220-230**, dedicated equipment for a video conference room **240**, and a telephony device **250**. Each client device **220-250** communicates with the video conference provider **210** over a communications network, such as the internet for client devices **220-240** or the PSTN for client device **250**, generally as described above with respect to FIG. **1**. The video conference provider **210** is also in communication with one or more user identity providers **215**, which can authenticate various users to the video conference provider **210** generally as described above with respect to FIG. **1**.

[0049] In this example, the video conference provider **210** employs multiple different servers (or groups of servers) to provide different aspects of video conference functionality, thereby enabling

the various client devices to create and participate in video conference meetings. The video conference provider **210** uses one or more real-time media servers **212**, one or more network services servers **214**, one or more video room gateways **216**, and one or more telephony gateways **218**. Each of these servers **212-218** is connected to one or more communications networks to enable them to collectively provide access to and participation in one or more video conference meetings to the client devices **220-250**.

[0050] The real-time media servers **212** provide multiplexed multimedia streams to meeting participants, such as the client devices **220-250** shown in FIG. 2. While video and audio streams typically originate at the respective client devices, they are transmitted from the client devices **220-250** to the video conference provider **210** via one or more networks where they are received by the real-time media servers **212**. The real-time media servers **212** determine which protocol is optimal based on, for example, proxy settings and the presence of firewalls, etc. For example, the client device might select among UDP, TCP, TLS, or HTTPS for audio and video and UDP for content screen sharing.

[0051] The real-time media servers **212** then multiplex the various video and audio streams based on the target client device and communicate multiplexed streams to each client device. For example, the real-time media servers **212** receive audio and video streams from client devices **220-240** and only an audio stream from client device **250**. The real-time media servers **212** then multiplex the streams received from devices **230-250** and provide the multiplexed stream to client device **220**. The real-time media servers **212** are adaptive, for example, reacting to real-time network and client changes, in how they provide these streams. For example, the real-time media servers **212** may monitor parameters such as a client's bandwidth CPU usage, memory and network I/O as well as network parameters such as packet loss, latency and jitter to determine how to modify the way in which streams are provided.

[0052] The client device **220** receives the stream, performs any decryption, decoding, and demultiplexing on the received streams, and then outputs the audio and video using the client device's video and audio devices. In this example, the real-time media servers do not multiplex client device **220**'s own video and audio feeds when transmitting streams to it. Instead each client device **220-250** only receives multimedia streams from other client devices **220-250**. For telephony devices that lack video capabilities, e.g., client device **250**, the real-time media servers **212** only deliver multiplex audio streams. The client device **220** may receive multiple streams for a particular communication, allowing the client device **220** to switch between streams to provide a higher quality of service.

[0053] In addition to multiplexing multimedia streams, the real-time media servers **212** may also decrypt incoming multimedia stream in some examples. As discussed above, multimedia streams may be encrypted between the client devices **220-250** and the video conference system **210**. In some such examples, the real-time media servers **212** may decrypt incoming multimedia streams, multiplex the multimedia streams appropriately for the various clients, and encrypt the multiplexed streams for transmission.

[0054] As mentioned above with respect to FIG. 1, the video conference provider **210** may provide certain functionality with respect to unencrypted multimedia streams at a user's request. For example, the meeting host may be able to request that the meeting be recorded or that a transcript of the audio streams be prepared, which may then be performed by the real-time media servers **212** using the decrypted multimedia streams, or the recording or transcription functionality may be off-loaded to a dedicated server (or servers), e.g., cloud recording servers, for recording the audio and video streams. In some examples, the video conference provider **210** may allow a meeting participant to notify it of inappropriate behavior or content in a meeting. Such a notification may trigger the real-time media servers to **212** record a portion of the meeting for review by the video conference provider **210**. Still other functionality may be implemented to take actions based on the decrypted multimedia streams at the video conference provider, such as monitoring video or audio

quality, adjusting or changing media encoding mechanisms, etc.

[0055] It should be appreciated that multiple real-time media servers **212** may be involved in communicating data for a single meeting and multimedia streams may be routed through multiple different real-time media servers **212**. In addition, the various real-time media servers **212** may not be co-located, but instead may be located at multiple different geographic locations, which may enable high-quality communications between clients that are dispersed over wide geographic areas, such as being located in different countries or on different continents. Further, in some examples, one or more of these servers may be co-located on a client's premises, e.g., at a business or other organization. For example, different geographic regions may each have one or more real-time media servers **212** to enable client devices in the same geographic region to have a high-quality connection into the video conference provider **210** via local servers **212** to send and receive multimedia streams, rather than connecting to a real-time media server located in a different country or on a different continent. The local real-time media servers **212** may then communicate with physically distant servers using high-speed network infrastructure, e.g., internet backbone network(s), that otherwise might not be directly available to client devices **220-250** themselves. Thus, routing multimedia streams may be distributed throughout the video conference system **210** and across many different real-time media servers **212**.

[0056] Turning to the network services servers **214**, these servers **214** provide administrative functionality to enable client devices to create or participate in meetings, send meeting invitations, create or manage user accounts or subscriptions, and other related functionality. Further, these servers may be configured to perform different functionalities or to operate at different levels of a hierarchy, e.g., for specific regions or localities, to manage portions of the video conference provider under a supervisory set of servers. When a client device **220-250** accesses the video conference provider **210**, it will typically communicate with one or more network services servers **214** to access their account or to participate in a meeting.

[0057] When a client device **220-250** first contacts the video conference provider **210** in this example, it is routed to a network services server **214**. The client device may then provide access credentials for a user, e.g., a username and password or single sign-on credentials, to gain authenticated access to the video conference provider **210**. This process may involve the network services servers **214** contacting a user identity provider **215** to verify the provided credentials. Once the user's credentials have been accepted, the client device **214** may perform administrative functionality, like updating user account information, if the user has an identity with the video conference provider **210**, or scheduling a new meeting, by interacting with the network services servers **214**.

[0058] In some examples, users may access the video conference provider **210** anonymously. When communicating anonymously, a client device **220-250** may communicate with one or more network services servers **214** but only provide information to create or join a meeting, depending on what features the video conference provider allows for anonymous users. For example, an anonymous user may access the video conference provider using client **220** and provide a meeting ID and passcode. The network services server **214** may use the meeting ID to identify an upcoming or on-going meeting and verify the passcode is correct for the meeting ID. After doing so, the network services server(s) **214** may then communicate information to the client device **220** to enable the client device **220** to join the meeting and communicate with appropriate real-time media servers **212**.

[0059] In cases where a user wishes to schedule a meeting, the user (anonymous or authenticated) may select an option to schedule a new meeting and may then select various meeting options, such as the date and time for the meeting, the duration for the meeting, a type of encryption to be used, one or more users to invite, privacy controls (e.g., not allowing anonymous users, preventing screen sharing, manually authorize admission to the meeting, etc.), meeting recording options, etc. The network services servers **214** may then create and store a meeting record for the scheduled

meeting. When the scheduled meeting time arrives (or within a threshold period of time in advance), the network services server(s) **214** may accept requests to join the meeting from various users.

[0060] To handle requests to join a meeting, the network services server(s) **214** may receive meeting information, such as a meeting ID and passcode, from one or more client devices **220-250**. The network services server(s) **214** locate a meeting record corresponding to the provided meeting ID and then confirm whether the scheduled start time for the meeting has arrived, whether the meeting host has started the meeting, and whether the passcode matches the passcode in the meeting record. If the request is made by the host, the network services server(s) **214** activates the meeting and connects the host to a real-time media server **212** to enable the host to begin sending and receiving multimedia streams.

[0061] Once the host has started the meeting, subsequent users requesting access will be admitted to the meeting if the meeting record is located and the passcode matches the passcode supplied by the requesting client device **220-250**. In some examples additional access controls may be used as well. But if the network services server(s) **214** determines to admit the requesting client device **220-250** to the meeting, the network services server **214** identifies a real-time media server **212** to handle multimedia streams to and from the requesting client device **220-250** and provides information to the client device **220-250** to connect to the identified real-time media server **212**. Additional client devices **220-250** may be added to the meeting as they request access through the network services server(s) **214**.

[0062] After joining a meeting, client devices will send and receive multimedia streams via the real-time media servers **212**, but they may also communicate with the network services servers **214** as needed during meetings. For example, if the meeting host leaves the meeting, the network services server(s) **214** may appoint another user as the new meeting host and assign host administrative privileges to that user. Hosts may have administrative privileges to allow them to manage their meetings, such as by enabling or disabling screen sharing, muting or removing users from the meeting, creating sub-meetings or “break-out” rooms, recording meetings, etc. Such functionality may be managed by the network services server(s) **214**.

[0063] For example, if a host wishes to remove a user from a meeting, they may identify the user and issue a command through a user interface on their client device. The command may be sent to a network services server **214**, which may then disconnect the identified user from the corresponding real-time media server **212**. If the host wishes to create a break-out room for one or more meeting participants to join, such a command may also be handled by a network services server **214**, which may create a new meeting record corresponding to the break-out room and then connect one or more meeting participants to the break-out room similarly to how it originally admitted the participants to the meeting itself.

[0064] In addition to creating and administering on-going meetings, the network services server(s) **214** may also be responsible for closing and tearing-down meetings once they have completed. For example, the meeting host may issue a command to end an on-going meeting, which is sent to a network services server **214**. The network services server **214** may then remove any remaining participants from the meeting, communicate with one or more real time media servers **212** to stop streaming audio and video for the meeting, and deactivate, e.g., by deleting a corresponding passcode for the meeting from the meeting record, or delete the meeting record(s) corresponding to the meeting. Thus, if a user later attempts to access the meeting, the network services server(s) **214** may deny the request.

[0065] Depending on the functionality provided by the video conference provider, the network services server(s) **214** may provide additional functionality, such as by providing private meeting capabilities for organizations, special types of meetings (e.g., webinars), etc. Such functionality may be provided according to various examples of video conferencing providers according to this description.

[0066] Referring now to the video room gateway servers **216**, these servers **216** provide an interface between dedicated video conferencing hardware, such as may be used in dedicated video conferencing rooms. Such video conferencing hardware may include one or more cameras and microphones and a computing device designed to receive video and audio streams from each of the cameras and microphones and connect with the video conference provider **210**. For example, the video conferencing hardware may be provided by the video conference provider to one or more of its subscribers, which may provide access credentials to the video conferencing hardware to use to connect to the video conference provider.

[0067] The video room gateway servers **216** provide specialized authentication and communication with the dedicated video conferencing hardware that may not be available to other client devices **220-230, 250**. For example, the video conferencing hardware may register with the video conference provider when it is first installed and the video room gateway may authenticate the video conferencing hardware using such registration as well as information provided to the video room gateway server(s) **216** when dedicated video conferencing hardware connects to it, such as device ID information, subscriber information, hardware capabilities, hardware version information etc. Upon receiving such information and authenticating the dedicated video conferencing hardware, the video room gateway server(s) **216** may interact with the network services servers **214** and real-time media servers **212** to allow the video conferencing hardware to create or join meetings hosted by the video conference provider **210**.

[0068] Referring now to the telephony gateway servers **218**, these servers **218** enable and facilitate telephony devices' participation in meetings hosted by the video conference provider. Because telephony devices communicate using the PSTN and not using computer networking protocols, such as TCP/IP, the telephony gateway servers **218** act as an interface that converts between the PSTN and the networking system used by the video conference provider **210**.

[0069] For example, if a user uses a telephony device to connect to a meeting, they may dial a phone number corresponding to one of the video conference provider's telephony gateway servers **218**. The telephony gateway server **218** will answer the call and generate audio messages requesting information from the user, such as a meeting ID and passcode. The user may enter such information using buttons on the telephony device, e.g., by sending dual-tone multi-frequency ("DTMF") audio signals to the telephony gateway server **218**. The telephony gateway server **218** determines the numbers or letters entered by the user and provides the meeting ID and passcode information to the network services servers **214**, along with a request to join or start the meeting, generally as described above. Once the telephony client device **250** has been accepted into a meeting, the telephony gateway server **218** is instead joined to the meeting on the telephony device's behalf.

[0070] After joining the meeting, the telephony gateway server **218** receives an audio stream from the telephony device and provides it to the corresponding real-time media server **212**, and receives audio streams from the real-time media server **212**, decodes them, and provides the decoded audio to the telephony device. Thus, the telephony gateway servers **218** operate essentially as client devices, while the telephony device operates largely as an input/output device, e.g., a microphone and speaker, for the corresponding telephony gateway server **218**, thereby enabling the user of the telephony device to participate in the meeting despite not using a computing device or video.

[0071] It should be appreciated that the components of the video conference provider **210** discussed above are merely examples of such devices and an example architecture. Some video conference providers may provide more or less functionality than described above and may not separate functionality into different types of servers as discussed above. Instead, any suitable servers and network architectures may be used according to different examples.

[0072] Referring now to FIG. 3, FIG. 3 illustrates a simplified system **300** that enables the users to engage in an end-to-end ("E2E") encrypted video conference. The system includes two client devices **320, 330** and a video conference provider **310**. The client devices **320, 330** are connected

to the video conference provider **310** through one or more communication networks (not shown), generally as described above with respect to FIGS. **1** and **2**.

[0073] In an E2E-encrypted video conference, each participant joins the video conference with their respective client device **320-330** and the host establishes a meeting key, e.g., a symmetric cryptographic key, that will be used to encrypt and decrypt the audio and video streams. Each of the participants also has their own respective public/private key pair that can be used to communicate with the respective participant and each participant's public key is published or distributed in any suitable manner, such as by registering it with a trusted entity or by generating a cryptographic signature using a private key and allowing the host or other participants to use a published copy of the public key to verify the signature.

[0074] Once each participant's public key has been verified, the host can securely distribute the meeting key to the participants by encrypting the meeting key using the participant's respective public keys. For example, the host may generate and send an encrypted message including the meeting key to each participant using the respective participant's public key. Upon receiving successfully decrypting the meeting key, the respective participants are then able to encrypt and decrypt meeting content.

[0075] In system **300** shown in FIG. **3**, client device **320** initially connects to the video conference provider **310** and requests that the video conference provider create a new meeting. Once the meeting is created, client device **320** is designated as the host of the meeting and establishes a meeting key to use to provide for E2E encryption in the meeting, but does not provide it to the video conference provider **310**. Subsequently, a participant client device **330** joins the meeting and generates and provides a cryptographically signed message using its private key to the host client device **320**, which verifies the message using the participant's public key. After verifying the public key, the host client device **320** encrypts the meeting key using the participant's public key and transmits it to the participant client device **330**, which decrypts the meeting key. Once the meeting key has been successfully received and decrypted by the participant client device **330**, it may begin transmitting encrypted audio and video using the meeting key.

[0076] In this example, each participant generates a per-stream encryption key by computing a new key using a non-secret stream ID for each data stream it transmits (e.g., audio and video), and uses the corresponding stream encryption key to encrypt its audio and video stream(s). The video conference provider receives the various encrypted streams, multiplexes them generally as described above with respect to FIGS. **1** and **2**, and distributes them to the various participating client devices **320, 330**. The respective client devices **320, 330** can then use the meeting key to decrypt the incoming streams and view the content of the video conference.

[0077] However, as part of this process, the video conference provider **310** does not have access to the meeting key. Thus, the video conference provider **310** is unable to decrypt the various audio and video streams. But because the individual streams are separately received from the various participants, the video conference provider **310** is able to identify the source of each stream and therefore it can properly multiplex the streams for delivery to each participant.

[0078] A consequence of the video conference provider **310** lacking access to the meeting key is that it cannot decrypt the audio and video streams to record them. Further, and as alluded to above, the meeting key is discarded by the various clients once the meeting has ended. Thus, recording meetings in an E2E-encrypted meeting becomes problematic.

[0079] To enable recording and later playback of an E2E-encrypted meeting, the host client device **320** may send a message to the video conference provider to record the meeting. The host client device **320** may then encrypt the meeting key using one key of an encryption key pair and send the encrypted meeting key to the video conference provider **310**. The video conference provider **310** receives the encrypted meeting key and associates it with the meeting. It also begins storing the encrypted audio and video streams from the various participants. Once the meeting concludes, the host or a participant may request the recorded encrypted audio and video data as well as the

encrypted meeting key from the video conference provider **310**.

[0080] The requesting client device can then decrypt the meeting key, so long as it has access to the other key of the encryption key pair used to encrypt the meeting key. Once it has access to the meeting key, it may decrypt the audio and video data and perform any additional processing needed on the data, such as encoding it into a suitable format, e.g., mp4.

[0081] FIG. **4** shows another example system **400** for securely recording and retrieving encrypted video conferences. In this example, the host's client device **420** is connected to a private network **440** within the host's company or organization, which is a customer of the video conference provider **410**. The customer also maintains a server **450** that can provide encryption key information and can perform decryption and encoding functionality on decrypted audio and video.

[0082] In this example, when the host's client device **420** establishes the meeting, it generates and distributes the meeting key generally as discussed above with respect to FIG. **3**. In addition, it also requests a key from the customer server **450**, which generates a new encryption key pair and provides one of the keys (referred to as the "public" key of the key pair) to the host's client device. The public key is then used to encrypt the meeting key. The encrypted meeting key is then provided to the video conference provider **410** as discussed above with respect to FIG. **3**. However, the second key (the "private" or "secret" key) is maintained by the server **450**, associated with the meeting, and not shared with the host's client device **420**.

[0083] Once the meeting has concluded, the customer's server **450** can request the encrypted meeting recording and the encrypted meeting key from the video conference provider **410**. The server **450** then decrypts the meeting key using the private key. It then uses the decrypted meeting key to decrypt the meeting recording. This allows the customer to maintain control over the recording because only it can decrypt the encrypted meeting key and the meeting recording. Further, it enables the customer to push computationally expensive processing to dedicated resources, such as a cloud environment, where the decryption and video/audio encoding can be performed, and it can store the decrypted, encoded recording at any suitable location for later retrieval by authorized personnel. Because this process is performed by the customer's server **450** (or other of the customer's computing resources), rather than one of the participants, the customer is able to maintain security over the meeting recording and only allow access to appropriate personnel within the customer's organization.

[0084] Referring now to FIG. **5**, FIG. **5** shows an example method **500** for securely recording and retrieving encrypted video conferences. The method **500** of FIG. **5** will be described with respect to the systems shown in FIG. **4**; however any suitable system according to this disclosure may be employed, including any of the systems shown in FIGS. **1-3** or **8**.

[0085] At block **510**, the host's client device **420** obtains a meeting cryptographic key. Any suitable technique for generating a meeting cryptographic key may be employed. For example, the meeting cryptographic key may include a cryptographic key pair generated according to any suitable cryptographic key pair technique, such as using elliptic curves. In some examples, the meeting cryptographic key may be a single cryptographic key.

[0086] At block **520**, the host's client device **420** transmits a request to the video conference provider **410** to initiate an encrypted video conference. The request may identify certain meeting information, such as a meeting identifier and passcode. It may also include one or more options for the meeting, including an option to employ E2E encryption. Alternatively, the request to employ E2E encryption may be sent separately from the request to initiate the meeting.

[0087] At block **530**, the host's client device **420** distributes the meeting cryptographic key to each participant of the plurality of participants. For example, the host's client device may obtain public cryptographic keys from each participant in the encrypted video conference and, for each participant, encrypt a copy of the meeting cryptographic key using the respective participant's public key. The host's client device **420** may then transmit each encrypted meeting cryptographic key to the respective participant based on the public key used.

[0088] At block **540**, the host's client device **420** obtains a public cryptographic key of a cryptographic key pair. As at block **510**, any suitable technique for generating a cryptographic key pair may be employed. In this example, a key pair is generated using an elliptic curve function and the host's client device **420** obtains one of the cryptographic keys of the cryptographic key pair, which becomes the public cryptographic key. Further, in this example, the host's client device **420** requests the public cryptographic key from a remote computing device, such as the customer server **450**. In some examples, however, the host's client device **420** itself may generate the cryptographic key pair and designate one of the cryptographic keys as the public key.

[0089] At block **550**, the host's client device **420** encrypts the meeting cryptographic key using the public cryptographic key.

[0090] At block **560**, the host's client device **420** transmits a request to the video conference provider **410** to record the video conference. In some examples, the request to record the video conference may be sent during the course of the video conference, while in some examples, the request to record may be sent prior to the meeting being initiated or may be configured as a meeting setting with the video conference provider **410** when the meeting is initially scheduled. Further, in some examples, the video conference provider **410** only allows the use of encrypted video conferences, in which case no request is transmitted.

[0091] At block **570**, the host's client device **420** transmits the encrypted meeting cryptographic key to the video conference provider **410**. In this example, the host's client device **420** transmits the encrypted meeting cryptographic key along with additional information to help associate the encrypted meeting cryptographic key, such as the meeting identifier, the date and time of the meeting, and the name of the host. However, in some examples, the host's client device **420** only transmits the encrypted meeting cryptographic key, and the video conference provider **410** maintains an association between the received encrypted meeting cryptographic key and the video conference.

[0092] In examples where the meeting cryptographic key changes during the video conference, the host's client device **420** may also transmit a notification to the video conference provider **410** an indication that the meeting cryptographic key has changed and a corresponding timestamp of when the participants changed to use the new meeting cryptographic key. In some examples, however, transmitting a new meeting cryptographic key provides the notification that the meeting cryptographic key has changed.

[0093] At block **580**, the host's client device **420** begins encrypting audio and video obtained from a microphone and video capture device using the meeting cryptographic key. In this example, the video conference provider transmits a message to the participants to begin encrypting audio and video; however, in some examples, the participants, including the host, may begin encrypting audio and video immediately upon receiving the meeting cryptographic key.

[0094] At block **582**, the host's client device **420** transmits the encrypted audio and video to the video conference provider **410**. It also begins to receive multiplexed streams of audio and video from the video conference provider from the other participants. It should be appreciated that the functionality at blocks **570** and **580** continues throughout the video conference.

[0095] At block **584**, the host's client device **420** obtains a new meeting cryptographic key generally as described above with respect to block **510** and then distributes the new meeting cryptographic key to the other participants generally as described above with respect to block **530**. In some examples, the host's client device may periodically change meeting cryptographic keys, e.g., every 5 minutes, or it may continue to use the same meeting cryptographic key throughout the course of the video conference. In such an example, blocks **584** and **586** are not performed.

[0096] At block **586**, the host's client device **420** encrypts the new meeting cryptographic key using the public cryptographic key generally as described above with respect to block **550**, and the method returns to block **570**.

[0097] It should be appreciated that the method **500** described above is only one example according

to this disclosure. In other examples, the blocks described above may be performed in a different order or one or more blocks may be omitted. For example, the order of blocks **520-570** may occur in any suitable order according to different examples.

[0098] Referring now to FIG. **6**, FIG. **6** shows an example method **600** for securely recording and retrieving encrypted video conferences. The method **600** of FIG. **6** will be described with respect to the systems shown in FIG. **4**; however any suitable system according to this disclosure may be employed, including any of the systems shown in FIGS. **1-3** or **8**.

[0099] At block **610**, the customer server **450** transmits a request to the video conference provider **410** to obtain recorded encrypted audio and video from a video conference and to obtain the corresponding encrypted meeting cryptographic key(s). In this example, the customer server **450** includes a meeting identifier, a meeting passcode, a host name, and the date and time when the meeting was scheduled to begin. In other examples, different information may be used. In some examples, the customer server **450** may provide credentials to access a customer account with the video conference provider **410**. Once the customer server **450** has access to the customer account, it may be presented with available encrypted meeting recordings to select for retrieval. In response to the request, the video conference provider **410** transmits the recorded encrypted audio, video, and meeting cryptographic key(s).

[0100] In examples where multiple meeting cryptographic keys were used during a video conference, the customer server **450** may also obtain an indication from the video conference provider **410** regarding when each meeting cryptographic key began being used, e.g., by providing a timestamp corresponding to each meeting cryptographic key.

[0101] It should be appreciated that while the functionality described with respect to block **610** is made with respect to the customer server **450**, any suitable computing device may perform such functionality, such as the host's client device **420**.

[0102] At block **620**, the customer server **450** decrypts the meeting cryptographic key(s). To do so, it accesses a key management system ("KMS") resident on the server **450** or at a remote computing device and requests the private cryptographic key corresponding to the public cryptographic key used to encrypt the meeting cryptographic key. In this example, the KMS maintains a record corresponding to each cryptographic key pair it manages along with corresponding meeting information, such as a meeting identifier, meeting host, a date and time when the meeting was scheduled to begin, etc. The customer server **450** supplies the necessary information to the KMS and receives, in response, the corresponding private cryptographic key, which it then uses to decrypt the meeting cryptographic key(s).

[0103] In some examples, block **620** may be performed by the host's client device **420** after the meeting has ended. As discussed above with respect to FIG. **5**, in some examples, the host's client device **420** may generate the cryptographic key pair used to encrypt the meeting cryptographic key(s). In which case, the host's client device **420** may use the corresponding private key to decrypt the meeting cryptographic key(s).

[0104] At block **630**, the customer server **450** decrypts the encrypted audio and video using the decrypted meeting cryptographic key(s). As discussed above with respect to FIG. **5**, in some examples, the same meeting cryptographic key is used throughout the video conference, in which case, the customer server **450** decrypts the entire video conference using the same meeting cryptographic key. However, if multiple meeting cryptographic keys were used, the customer server **450** uses information supplied by the video conference provider **410**, such as described above with respect to block **610**, to decrypt the encrypted video and audio using the corresponding key. And while in this example, block **630** was performed by a customer server **450**, in some examples, it may be performed by the host's client device **420**.

[0105] Referring now to FIG. **7**, FIG. **7** shows an example method **700** for securely recording and retrieving encrypted video conferences. The method **700** of FIG. **7** will be described with respect to the systems shown in FIG. **4**; however any suitable system according to this disclosure may be

employed, including any of the systems shown in FIGS. 1-3 or 8.

[0106] At block **710**, the video conference provider **410** initiates an encrypted video conference. In this example the encrypted video conference is initiated in response to a request received from a host client device **420**; however, in some examples, the video conference provider **410** may initiate the encrypted video conference without such a request, e.g., by initiating the encrypted video conference at a scheduled meeting time, or in response to a request from a participant's client device **430** that is not the host.

[0107] At block **720**, the video conference provider **410** receives and stores encrypted audio and video from the participants in the encrypted video conference. As discussed above with respect to FIG. 5, the host's client device **420** generates and distributes a meeting key to the various participants to enable them each to encrypted audio and video transmitted as a part of the encrypted video conference. In this example, the video conference provider **410** receives a request from the host's client device to record the meeting; however, in other examples, the video conference provider **410** initiates recording without a request, e.g., based on configuration settings for the video conference or based on a default requirement to record all video conferences.

[0108] To store the encrypted audio and video in this example, the video conference provider **410** stores the encrypted audio and video received from the participants in a data store and associates the stored encrypted audio and video with the video conference. For example, the video conference provider **410** may store additional information with the encrypted audio and video, which may include one or more of the following: a reference to a video conference record stored in by the video conference provider, the video conference meeting identifier, the date and time that the video conference was scheduled to begin, the host's name, a host account identifier, a customer identifier, etc.

[0109] At block **730**, the video conference provider **410** provides multiplexed encrypted streams of audio and video the participants. Despite the various audio and video streams being encrypted, the video conference provider **410** can determine the origin of each audio and video stream, e.g., based on a network connection or port on which the respective stream was received or based on unencrypted information transmitted along with the audio and video streams, such information about the participant or client device that generated the audio or video stream. To multiplex the audio and video, the video conference providers **410** accepts the encrypted audio and video streams from the various participants and, for each participant, transmits the audio and video streams from the other participants to the respective participant to each participant receives the audio and video streams from the other participants. In some examples, the video conference provider **410** may also transmit the audio and video stream from the participant itself so that every participant receives all audio and video streams.

[0110] At block **740**, the video conference provider **410** receives and stores an encrypted meeting cryptographic key. As discussed above with respect to FIG. 5, the host client device **420** generates and distributes a meeting cryptographic key that the participants can use to encrypt the audio and video transmitted during the video conference, and that the host client device **420** encrypts the meeting cryptographic key. The video conference provider **410** receives the encrypted meeting cryptographic key and stores it in a data store.

[0111] At block **750**, the video conference provider associates the encrypted audio and video with the encrypted meeting cryptographic key. For example, as discussed above, the video conference provider **410** may associate the stored encrypted audio and video with information to identify the corresponding video conference. The video conference provider **410** may similarly associate the encrypted meeting cryptographic key with the video conference or the stored encrypted audio and video, such as by storing additional information as described above with respect to block **720** or by storing the encrypted meeting cryptographic key in a data store record corresponding to the video conference.

[0112] In some examples, the video conference provider **410** may receive multiple encrypted

meeting cryptographic keys during the course of an encrypted video conference, as discussed above with respect to FIGS. 5 and 6. In response to receiving successive encrypted meeting cryptographic keys, the video conference provider **410** stores each such received key and associates it with the encrypted audio and video as discussed above. In some examples, the video conference provider **410** may also receive indications identifying when each encrypted meeting cryptographic key began being used, e.g., by providing a corresponding timestamp. Such additional information may also be stored and associated with the encrypted audio and video.

[0113] At block **760**, the video conference provider **410** receives a request for the stored encrypted audio and video and for the encrypted meeting cryptographic key(s). In this example, the video conference provider **410** only will accept requests for the stored encrypted information once the video conference has concluded. However, in some examples, such requests may be received while the video conference is on-going. Further, in some examples, the video conference provider **410** may only provide the stored encrypted information to an authorized user, e.g., to the host of the video conference or to a user associated with an account associated with the stored encrypted information.

[0114] At block **770**, the video conference provider **410** provides the stored encrypted audio and video and the stored encrypted meeting cryptographic key(s) in response to the request. Further, if additional information is available, such as transition timestamps between meeting encryptions keys, the video conference provider **410** may also provide such information in response to a request for the stored audio and video and the stored encrypted meeting cryptographic key.

[0115] Referring now to FIG. 8, FIG. 8 shows another example system **800** for securely recording and retrieving encrypted video conferences. This example system **800** includes a host client device **820** and a participant client device **830**. The host client device **820** communicates with the video conference provider **810** to initiate a new video conference. In this example, however, rather than sending a message to the video conference provider to record the encrypted audio and video, instead, the host has invited an automated account to join the video conference as a participant and record the video conference. For example, the host's client device **820** may be connected to a private network **840** at their place of employment, which is a customer of the video conference provider **810**, and may transmit a message to the customer server **450** notifying it of the meeting and providing information to enable it to access the video conference, e.g., a meeting identifier, a passcode, and a scheduled date and time for the meeting. The customer server **450** may then, at the scheduled time, cause an automated process to connect to the video conference using the supplied meeting identifier and passcode.

[0116] Once the automated process is connected to the video conference provider and joins the meeting, it will be treated as a participant by the video conference provider **810** and will receive meeting cryptographic keys as any other participant would, generally as described above with respect to FIGS. 4-5. Because the automated process has access to the unencrypted audio and video by using the meeting key, it can record the audio and video and encode it into a suitable format, e.g., mp4, for subsequent distribution. Thus, the system **800** can enable recording of E2E-encrypted video conferences without opening the video conference to the video conference provider **810** to record.

[0117] Referring now to FIG. 9, FIG. 9 shows an example method **900** for securely recording and retrieving encrypted video conferences. The method **900** of FIG. 9 will be described with respect to the system shown in FIG. 8; however any suitable system according to this disclosure may be employed, including any of the systems shown in FIGS. 1-3.

[0118] At block **910**, the host's client device **820** obtains a meeting cryptographic key generally as described above with respect to block **510** in FIG. 5.

[0119] At block **920**, the host's client device **820** transmits a request to initiate an encrypted video conference generally as described above with respect to block **520**.

[0120] At block **930**, the host's client device **820** transmits a request to record the video conference

to the customer server **850**. In this example, the client device **820** transmits the request once the meeting has begun. The request includes information to enable the customer server **850** to join the video conference, such as a meeting identifier and passcode or a URL link to the meeting. The request also indicates whether the meeting has started or include a scheduled start time for the meeting. In response to the request, the customer server **850** causes an automated process, e.g., customer meeting recorder **852**, to join the video conference using the supplied information, e.g., the meeting identifier and passcode.

[0121] At block **940**, the host's client device **820** distributes the meeting cryptographic key to the meeting participants generally as described above with respect to block **530**. Because the customer meeting recorder **852** discussed above has joined the video conference as a participant, it will also receive a copy of the meeting cryptographic key and can therefore receive and decrypt the encrypted audio and video of the video conference.

[0122] At block **950**, the host's client device **820**, as well as the other participants, e.g., client device **830**, encrypt the audio and video captured by the host's client device's microphone and camera using the meeting cryptographic key generally as described above with respect to block **580**.

[0123] At block **960**, the host's client device **820**, as well as the other participants, transmits its encrypted audio and video to the video conference provider **810**, generally as described above with respect to block **582**.

[0124] At block **970**, each participant decrypts received encrypted audio and video. In particular, the customer meeting recorder **852** receives and decrypts encrypted audio and video from the various meeting participants, optionally encodes it into a suitable format, and stores the decrypted audio and video (encoded or not) onto a data store, such as its own local data store or at a remote computing device, e.g., customer server **450**.

[0125] At block **980**, the host's client device **820** optionally obtains a new meeting cryptographic key generally as described above with respect to block **584**, and, transitions the participants to the new meeting cryptographic key.

[0126] Once the meeting has concluded, the customer meeting recorder **852** can store the recorded audio and video to a suitable location for subsequent authorized retrieval. Because the recording was handled entirely by the customer itself, it is able to control the access to the recording and ensure that only authorized users are able to access its contents.

[0127] Referring now to FIG. **10**, FIG. **10** shows an example method **900** for securely recording and retrieving encrypted video conferences. The method **900** of FIG. **9** will be described with respect to the system shown in FIG. **4**; however any suitable system according to this disclosure may be employed, including any of the systems shown in FIGS. **1-3** or **8**.

[0128] Blocks **1010-1030** are performed generally as described above with respect to blocks **510-530** in FIG. **5**.

[0129] At block **1040**, the host's client device **420** transmits the meeting cryptographic key to the customer server **450** to store in a secure database, e.g., an encrypted database, along with information to identify the video conference, e.g., a meeting identifier, passcode, scheduled start time for the video conference, the host's name, a customer account with the video conference provider, etc. Such information is also stored in the secure database and associated with the meeting cryptographic key. In some examples, the meeting cryptographic key may be separately encrypted, such as by using the process described above with respect to FIG. **5** in which the host's client device requests a public cryptographic key from the customer server. If the meeting cryptographic key is encrypted, the customer server **450** may also store a reference to the corresponding private cryptographic key to enable decrypting of the meeting cryptographic key.

[0130] At block **1050**, the host's client device **420** transmits a request to record the meeting to the video conference provider **410** generally as described above with respect to block **560**. In this example, however, the host's client device **420** does not transmit an encrypted copy of the meeting

cryptographic key to the video conference provider **410**. Instead, as discussed above, the meeting cryptographic key has been stored by the customer server **450**.

[0131] Blocks **1060** through **1090** proceed generally as described above with respect to blocks **582-584**; however, in the event a new meeting cryptographic key is generated, it is provided to the customer server **450** to be stored as described above with respect to block **1040**, rather than to the video conference provider **410**.

[0132] Once the video conference has concluded, the customer server **450** may request a copy of the encrypted audio and video, generally as described in blocks **610-630** of FIG. **6**; however, because the meeting cryptographic key(s) are stored by the customer server **450**, it does not request them from the video conference provider **410**.

[0133] Referring now to FIG. **11**, FIG. **11** shows an example computing device **1100** suitable for use in example systems or methods for suggesting user actions during a video conference according to this disclosure. The example computing device **1100** includes a processor **1110** which is in communication with the memory **1120** and other components of the computing device **1100** using one or more communications buses **1102**. The processor **1110** is configured to execute processor-executable instructions stored in the memory **1120** to execute an intuitive assistant **1100** according to this disclosure or to perform one or more methods for suggesting user actions during a video conference according to different examples, such as part or all of the example methods **500-700**, **900**, **1000** described above with respect to FIGS. **5-7**, **9**, and **10**. The computing device, in this example, also includes one or more user input devices **1150**, such as a keyboard, mouse, touchscreen, video capture device, microphone, etc., to accept user input. The computing device **1100** also includes a display **1140** to provide visual output to a user.

[0134] The computing device **1100** also includes a communications interface **1140**. In some examples, the communications interface **1130** may enable communications using one or more networks, including a local area network (“LAN”); wide area network (“WAN”), such as the Internet; metropolitan area network (“MAN”); point-to-point or peer-to-peer connection; etc. Communication with other devices may be accomplished using any suitable networking protocol. For example, one suitable networking protocol may include the Internet Protocol (“IP”), Transmission Control Protocol (“TCP”), User Datagram Protocol (“UDP”), or combinations thereof, such as TCP/IP or UDP/IP.

[0135] While some examples of methods and systems herein are described in terms of software executing on various machines, the methods and systems may also be implemented as specifically-configured hardware, such as field-programmable gate array (FPGA) specifically to execute the various methods according to this disclosure. For example, examples can be implemented in digital electronic circuitry, or in computer hardware, firmware, software, or in a combination thereof. In one example, a device may include a processor or processors. The processor comprises a computer-readable medium, such as a random access memory (RAM) coupled to the processor. The processor executes computer-executable program instructions stored in memory, such as executing one or more computer programs. Such processors may comprise a microprocessor, a digital signal processor (DSP), an application-specific integrated circuit (ASIC), field programmable gate arrays (FPGAs), and state machines. Such processors may further comprise programmable electronic devices such as PLCs, programmable interrupt controllers (PICs), programmable logic devices (PLDs), programmable read-only memories (PROMs), electronically programmable read-only memories (EPROMs or EEPROMs), or other similar devices.

[0136] Such processors may comprise, or may be in communication with, media, for example one or more non-transitory computer-readable media, that may store processor-executable instructions that, when executed by the processor, can cause the processor to perform methods according to this disclosure as carried out, or assisted, by a processor. Examples of non-transitory computer-readable medium may include, but are not limited to, an electronic, optical, magnetic, or other storage device capable of providing a processor, such as the processor in a web server, with processor-

executable instructions. Other examples of non-transitory computer-readable media include, but are not limited to, a floppy disk, CD-ROM, magnetic disk, memory chip, ROM, RAM, ASIC, configured processor, all optical media, all magnetic tape or other magnetic media, or any other medium from which a computer processor can read. The processor, and the processing, described may be in one or more structures, and may be dispersed through one or more structures. The processor may comprise code to carry out methods (or parts of methods) according to this disclosure.

[0137] The foregoing description of some examples has been presented only for the purpose of illustration and description and is not intended to be exhaustive or to limit the disclosure to the precise forms disclosed. Numerous modifications and adaptations thereof will be apparent to those skilled in the art without departing from the spirit and scope of the disclosure.

[0138] Reference herein to an example or implementation means that a particular feature, structure, operation, or other characteristic described in connection with the example may be included in at least one implementation of the disclosure. The disclosure is not restricted to the particular examples or implementations described as such. The appearance of the phrases “in one example,” “in an example,” “in one implementation,” or “in an implementation,” or variations of the same in various places in the specification does not necessarily refer to the same example or implementation. Any particular feature, structure, operation, or other characteristic described in this specification in relation to one example or implementation may be combined with other features, structures, operations, or other characteristics described in respect of any other example or implementation.

[0139] Use herein of the word “or” is intended to cover inclusive and exclusive OR conditions. In other words, A or B or C includes any or all of the following alternative combinations as appropriate for a particular usage: A alone; B alone; C alone; A and B only; A and C only; B and C only; and A and B and C.

## Claims

1. A method comprising: receiving, from a client device, a request for an encryption key for an end-to-end (E2E)-encrypted virtual conference hosted by a virtual conference provider; generating a cryptographic key pair comprising first and second cryptographic keys; transmitting the first cryptographic key to the client device; responsive to receiving an indication that the E2E-encrypted virtual conference has ended, requesting and receiving an encrypted recording and encrypted meeting key from the virtual conference provider, the encrypted meeting key encrypted based on the first cryptographic key; storing the encrypted recording and the encrypted meeting key; and storing a correspondence between the second cryptographic key and the encrypted meeting key.
2. The method of claim 1, further comprising: receiving, from a second client device, a request for the encrypted recording and the encrypted meeting key; and transmitting the encrypted recording and the encrypted meeting key.
3. The method of claim 2, further comprising determining whether the request is received from an authorized user, and wherein the transmitting the encrypted recording and the encrypted meeting key is responsive to determining that the user is authorized.
4. The method of claim 1, further comprising: decrypting the encrypted meeting key using the second cryptographic key; and decrypting the encrypted recording using the decrypted meeting key.
5. The method of claim 4, wherein decrypting the encrypted recording comprises transmitted the encrypted recording and the decrypted meeting key to a remote server.
6. The method of claim 1, wherein receiving the encrypted recording and the encrypted meeting key comprises receiving a plurality of encrypted meeting keys for the E2E-encrypted virtual conference and one or more indications of corresponding portions of the encrypted recording for

each encrypted meeting key.

**7.** The method of claim 6, further comprising: decrypting each encrypted meeting key of the plurality of encrypted meeting keys using the second cryptographic key; and decrypting the encrypted recording using the respective decrypted meeting key based on the one or more indications.

**8.** A system comprising: a non-transitory computer-readable medium; a communications interface; and a processor communicatively coupled to the non-transitory computer-readable medium and the communications interface, the processor configured to execute processor-executable instructions stored in the non-transitory computer-readable medium to: receiving, from a client device, a request for an encryption key for an end-to-end (E2E)-encrypted virtual conference hosted by a virtual conference provider; generating a cryptographic key pair comprising first and second cryptographic keys; transmitting the first cryptographic key to the client device; responsive to receiving an indication that the E2E-encrypted virtual conference has ended, requesting and receiving an encrypted recording and encrypted meeting key from the virtual conference provider, the encrypted meeting key encrypted based on the first cryptographic key; storing the encrypted recording and the encrypted meeting key; and storing a correspondence between the second cryptographic key and the encrypted meeting key.

**9.** The system of claim 8, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: receive, from a second client device, a request for the encrypted recording and the encrypted meeting key; and transmit the encrypted recording and the encrypted meeting key.

**10.** The system of claim 9, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: determine whether the request is received from an authorized user, and wherein the transmitting the encrypted recording and the encrypted meeting key is responsive to determining that the user is authorized.

**11.** The system of claim 8, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: decrypt the encrypted meeting key using the second cryptographic key; and decrypt the encrypted recording using the decrypted meeting key.

**12.** The system of claim 11, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to transmit the encrypted recording and the decrypted meeting key to a remote server to decrypt the encrypted recording.

**13.** The system of claim 8, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to receive a plurality of encrypted meeting keys for the E2E-encrypted virtual conference and one or more indications of corresponding portions of the encrypted recording for each encrypted meeting key.

**14.** The system of claim 13, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: decrypt each encrypted meeting key of the plurality of encrypted meeting keys using the second cryptographic key; and decrypt the encrypted recording using the respective decrypted meeting key based on the one or more indications.

**15.** A non-transitory computer-readable medium comprising processor-executable instructions configured to cause one or more processors to: receive, from a client device, a request for an encryption key for an end-to-end (E2E)-encrypted virtual conference hosted by a virtual conference provider; generate a cryptographic key pair comprising first and second cryptographic keys; transmit the first cryptographic key to the client device; responsive to receiving an indication that the E2E-encrypted virtual conference has ended, request and receive an encrypted recording and encrypted meeting key from the virtual conference provider, the encrypted meeting key encrypted based on the first cryptographic key; store the encrypted recording and the encrypted meeting key;

and store a correspondence between the second cryptographic key and the encrypted meeting key.

**16.** The non-transitory computer-readable medium of claim 15, further comprising processor-executable instructions configured to cause one or more processors to: receive, from a second client device, a request for the encrypted recording and the encrypted meeting key; and transmit the encrypted recording and the encrypted meeting key.

**17.** The non-transitory computer-readable medium of claim 16, further comprising processor-executable instructions configured to cause one or more processors to: determine whether the request is received from an authorized user, and wherein the transmitting the encrypted recording and the encrypted meeting key is responsive to determining that the user is authorized.

**18.** The non-transitory computer-readable medium of claim 15, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: decrypt the encrypted meeting key using the second cryptographic key; and decrypt the encrypted recording using the decrypted meeting key.

**19.** The non-transitory computer-readable medium of claim 15, further comprising processor-executable instructions configured to cause one or more processors to receive a plurality of encrypted meeting keys for the E2E-encrypted virtual conference and one or more indications of corresponding portions of the encrypted recording for each encrypted meeting key.

**20.** The non-transitory computer-readable medium of claim 19, wherein the processor is configured to execute further processor-executable instructions stored in the non-transitory computer-readable medium to: decrypt each encrypted meeting key of the plurality of encrypted meeting keys using the second cryptographic key; and decrypt the encrypted recording using the respective decrypted meeting key based on the one or more indications.

---
