BACKGROUND

[0002] Brain excitability is defined as the level of arousal of an animal, a continuum that ranges from coma to convulsions, and is regulated by various neurotransmitters. In general, neurotransmitters are responsible for regulating the conductance of ions across neuronal membranes. At rest, the neuronal membrane possesses a potential (or membrane voltage) of approximately -70 mV, the cell interior being negative with respect to the cell exterior. The potential (voltage) is the result of ion (K^+ , Na^+ , Cl^- , organic anions) balance across the neuronal semipermeable membrane. Neurotransmitters are stored in presynaptic vesicles and are released as a result of neuronal action potentials. When released into the synaptic cleft, an excitatory chemical transmitter such as acetylcholine will cause membrane depolarization (change of potential from -70 mV to -50 mV). This effect is mediated by postsynaptic nicotinic receptors which are stimulated by acetylcholine to increase the membrane permeability of Na^+ ions. The reduced membrane potential stimulates neuronal excitability in the form of a postsynaptic action potential.

[0003] NMDA receptors are highly expressed in the CNS and are involved in excitatory synaptic transmission and synaptic plasticity as well as excitotoxicity. These receptors are ligand-gated ion channels that admit Ca^{2+} after binding of the neurotransmitter glutamate and are fundamental to excitatory neurotransmission and normal CNS function. NMDA receptors are heteromeric complexes comprised of NR1, NR2, and/or NR3 subunits and possess distinct recognition sites for exogenous and endogenous ligands. These recognition sites include binding sites for glycine, and glutamate agonists and modulators. These modulators may be useful as therapeutic agents with potential clinical uses as cognitive enhancers and in the treatment of psychiatric disorders in which glutamatergic transmission is reduced or defective (see, e.g., Horak et al., *J. of Neuroscience*, 2004, 24(46), 10318-10325).

[0004] Neuroactive steroids such as pregnenolone sulfate (PS) have been shown to exert direct modulatory effects on several types of neurotransmitter receptors, such as $GABA_A$, glycine, AMPA-kainate, and NMDA receptors. NMDA receptors are positively modulated by PS; however, the degree of modulation varies considerably.

[0005] In addition to PS, several other 3β -hydroxy steroids have been shown to potentiate NMDA receptors (see, e.g., Paul et al., *J. Pharm. and Exp. Ther.* 1994, 271, 677-682). Recently, a 3β -hydroxy-ergost-5-ene steroid derivative (1) was reported as positive modulator of NMDA (NR1a/NR2A). Compound (1) (also referred to as Org-1) was found to selectively modulate NMDA over $GABA_A$ (see, e.g., Madau et al., Program No. 613.2/B87. 2009 Neuroscience Meeting Planner. Chicago, IL: Society for Neuroscience, 2009; Connick et al., Program No. 613.1/B86. 2009 Neuroscience Meeting Planner. Chicago, IL: Society for Neuroscience, 2009).

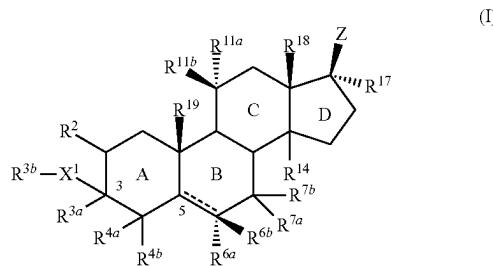

[0006] New and improved neuroactive steroids are needed that modulate brain excitability for the prevention and treatment of CNS-related conditions. The compounds, compositions, and methods described herein are directed toward this end.

Similarly, reference to intermediates, whether or not they themselves are claimed, is meant to embrace their salts, and solvates, where the context so permits.

[0126] These and other exemplary substituents are described in more detail in the Detailed Description, Examples, and claims. The invention is not intended to be limited in any manner by the above exemplary listing of substituents.

Other definitions

[0127] “Pharmaceutically acceptable” means approved or approvable by a regulatory agency of the Federal or a state government or the corresponding agency in countries other than the United States, or that is listed in the U.S. Pharmacopoeia or other generally recognized pharmacopoeia for use in animals, and more particularly, in humans.

[0128] “Pharmaceutically acceptable salt” refers to a salt of a compound of the invention that is pharmaceutically acceptable and that possesses the desired pharmacological activity of the parent compound. In particular, such salts are

non-toxic may be inorganic or organic acid addition salts and base addition salts. Specifically, such salts include: (1) acid addition salts, formed with inorganic acids such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid, and the like; or formed with organic acids such as acetic acid, propionic acid, hexanoic acid, cyclopentanepropionic acid, glycolic acid, pyruvic acid, lactic acid, malonic acid, succinic acid, malic acid, maleic acid, fumaric acid, tartaric acid, citric acid, benzoic acid, 3-(4-hydroxybenzoyl) benzoic acid, cinnamic acid, mandelic acid, methanesulfonic acid, ethanesulfonic acid, 1,2-ethane-disulfonic acid, 2-hydroxyethanesulfonic acid, benzenesulfonic acid, 4-chlorobenesulfonic acid, 2-naphthalenesulfonic acid, 4-toluenesulfonic acid, camphorsulfonic acid, 4-methylbicyclo[2.2.2]-oct-2-ene-1-carboxylic acid, glucoheptonic acid, 3-phenylpropionic acid, trimethylacetic acid, tertiary butylacetic acid, lauryl sulfuric acid, gluconic acid, glutamic acid, hydroxynaphthoic acid, salicylic acid, stearic acid, muconic acid, and the like; or (2) salts formed when an acidic proton present in the parent compound either is replaced by a metal ion, e.g., an alkali metal ion, an alkaline earth ion, or an aluminum ion; or coordinates with an organic base such as ethanolamine, diethanolamine, triethanolamine, N-methylglucamine and the like. Salts further include, by way of example only, sodium, potassium, calcium, magnesium, ammonium, tetraalkylammonium, and the like; and when the compound contains a basic functionality, salts of non toxic organic or inorganic acids, such as hydrochloride, hydrobromide, tartrate, mesylate, acetate, maleate, oxalate and the like. The term “pharmaceutically acceptable cation” refers to an acceptable cationic counter-ion of an acidic functional group. Such cations are exemplified by sodium, potassium, calcium, magnesium, ammonium, tetraalkylammonium cations, and the like (see, e.g., Berge, et al., *J. Pharm. Sci.* 66(1): 1-79 (Jan. "77)).

[0129] “Pharmaceutically acceptable vehicle” refers to a diluent, adjuvant, excipient or carrier with which a compound of the invention is administered.

[0130] “Pharmaceutically acceptable metabolically cleavable group” refers to a group which is cleaved in vivo to yield the parent molecule of the structural Formula indicated herein. Examples of metabolically cleavable groups include $-COR$, $-COOR$, $-CONRR$ and $-CH_2OR$ radicals, where R is selected independently at each occurrence from alkyl, trialkylsilyl, carbocyclic aryl or carbocyclic aryl substituted with one or more of alkyl, halogen, hydroxy or alkoxy. Specific examples of representative metabolically cleavable groups include acetyl, methoxycarbonyl, benzoyl, methoxymethyl and trimethylsilyl groups.

[0131] “Prodrugs” refers to compounds, including derivatives of the compounds of the invention, which have cleavable groups and become by solvolysis or under physiological conditions the compounds of the invention which are pharmaceutically active in vivo. Such examples include, but are not limited to, choline ester derivatives and the like, N-alkylmorpholine esters and the like. Other derivatives of the compounds of this invention have activity in both their acid and acid derivative forms, but in the acid sensitive form often offers advantages of solubility, tissue compatibility, or delayed release in the mammalian organism (see, Bundgard, H., Design of Prodrugs, pp. 7-9, 21-24, Elsevier, Amsterdam 1985). Prodrugs include acid derivatives well known to practitioners of the art, such as, for example, esters prepared

by reaction of the parent acid with a suitable alcohol, or amides prepared by reaction of the parent acid compound with a substituted or unsubstituted amine, or acid anhydrides, or mixed anhydrides. Simple aliphatic or aromatic esters, amides and anhydrides derived from acidic groups pendant on the compounds of this invention are particular prodrugs. In some cases it is desirable to prepare double ester type prodrugs such as (acyloxy)alkyl esters or ((alkoxycarbonyl)oxy)alkylesters. Particularly the C₁ to C₈ alkyl, C₂-C₈ alkenyl, C₂-C₈ alkynyl, aryl, C₇-C₁₂ substituted aryl, and C₇-C₁₂ arylalkyl esters of the compounds of the invention.

[0132] “Solvate” refers to forms of the compound that are associated with a solvent or water (also referred to as “hydrate”), usually by a solvolysis reaction. This physical association includes hydrogen bonding. Conventional solvents include water, ethanol, acetic acid and the like. The compounds of the invention may be prepared e.g. in crystalline form and may be solvated or hydrated. Suitable solvates include pharmaceutically acceptable solvates, such as hydrates, and further include both stoichiometric solvates and non-stoichiometric solvates. In certain instances the solvate will be capable of isolation, for example when one or more solvent molecules are incorporated in the crystal lattice of the crystalline solid. “Solvate” encompasses both solution-phase and isolable solvates. Representative solvates include hydrates, ethanolates and methanolates.

[0133] A “subject” to which administration is contemplated includes, but is not limited to, humans (i.e., a male or female of any age group, e.g., a pediatric subject (e.g., infant, child, adolescent) or adult subject (e.g., young adult, middle-aged adult or senior adult)) and/or a non-human animal, e.g., a mammal such as primates (e.g., cynomolgus monkeys, rhesus monkeys), cattle, pigs, horses, sheep, goats, rodents, cats, and/or dogs. In certain embodiments, the subject is a human. In certain embodiments, the subject is a non-human animal. The terms “human,” “patient,” and “subject” are used interchangeably herein.

[0134] An “effective amount” means the amount of a compound that, when administered to a subject for treating or preventing a disease, is sufficient to effect such treatment or prevention. The “effective amount” can vary depending on the compound, the disease and its severity, and the age, weight, etc., of the subject to be treated. A “therapeutically effective amount” refers to the effective amount for therapeutic treatment. A “prophylactically effective amount” refers to the effective amount for prophylactic treatment.

[0135] “Preventing” or “prevention” or “prophylactic treatment” refers to a reduction in risk of acquiring or developing a disease or disorder (i.e., causing at least one of the clinical symptoms of the disease not to develop in a subject not yet exposed to a disease-causing agent, or predisposed to the disease in advance of disease onset).

[0136] The term “prophylaxis” is related to “prevention,” and refers to a measure or procedure the purpose of which is to prevent, rather than to treat or cure a disease. Non-limiting examples of prophylactic measures may include the administration of vaccines; the administration of low molecular weight heparin to hospital patients at risk for thrombosis due, for example, to immobilization; and the administration of an anti-malarial agent such as chloroquine, in advance of a visit to a geographical region where malaria is endemic or the risk of contracting malaria is high.

[0137] “Treating” or “treatment” or “therapeutic treatment” of any disease or disorder refers, in one embodiment, to ameliorating the disease or disorder (i.e., arresting the disease or reducing the manifestation, extent or severity of at least one of the clinical symptoms thereof). In another embodiment “treating” or “treatment” refers to ameliorating at least one physical parameter, which may not be discernible by the subject. In yet another embodiment, “treating” or “treatment” refers to modulating the disease or disorder, either physically, (e.g., stabilization of a discernible symptom), physiologically, (e.g., stabilization of a physical parameter), or both. In a further embodiment, “treating” or “treatment” relates to slowing the progression of the disease.

[0138] As used herein, the term “isotopic variant” refers to a compound that contains unnatural proportions of isotopes at one or more of the atoms that constitute such compound. For example, an “isotopic variant” of a compound can contain one or more non-radioactive isotopes, such as for example, deuterium (²H or D), carbon-13 (¹³C), nitrogen-15 (¹⁵N), or the like. It will be understood that, in a compound where such isotopic substitution is made, the following atoms, where present, may vary, so that for example, any hydrogen may be ²H/D, any carbon may be ¹³C, or any nitrogen may be ¹⁵N, and that the presence and placement of such atoms may be determined within the skill of the art. Likewise, the invention may include the preparation of isotopic variants with radioisotopes, in the instance for example, where the resulting compounds may be used for drug and/or substrate tissue distribution studies. The radioactive isotopes tritium, i.e., ³H, and carbon-14, i.e., ¹⁴C, are particularly useful for this purpose in view of their ease of incorporation and ready means of detection. Further, compounds may be prepared that are substituted with positron emitting isotopes, such as ¹¹C, ¹⁸F, ¹⁵O and ¹³N, and would be useful in Positron Emission Tomography (PET) studies for examining substrate receptor occupancy. All isotopic variants of the compounds provided herein, radioactive or not, are intended to be encompassed within the scope of the invention.

[0139] It is also to be understood that compounds that have the same molecular formula but differ in the nature or sequence of bonding of their atoms or the arrangement of their atoms in space are termed “isomers.” Isomers that differ in the arrangement of their atoms in space are termed “stereoisomers.”

[0140] Stereoisomers that are not mirror images of one another are termed “diastereomers” and those that are non-superimposable mirror images of each other are termed “enantiomers.” When a compound has an asymmetric center, for example, it is bonded to four different groups, a pair of enantiomers is possible. An enantiomer can be characterized by the absolute configuration of its asymmetric center and is described by the R- and S-sequencing rules of Cahn and Prelog, or by the manner in which the molecule rotates the plane of polarized light and designated as dextrorotatory or levorotatory (i.e., as (+) or (-)-isomers respectively). A chiral compound can exist as either individual enantiomer or as a mixture thereof. A mixture containing equal proportions of the enantiomers is called a “racemic mixture”.

[0141] “Tautomers” refer to compounds that are interchangeable forms of a particular compound structure, and that vary in the displacement of hydrogen atoms and electrons. Thus, two structures may be in equilibrium through

the movement of π electrons and an atom (usually H). For example, enols and ketones are tautomers because they are rapidly interconverted by treatment with either acid or base. Another example of tautomerism is the aci- and nitro-forms of phenylnitromethane, that are likewise formed by treatment with acid or base. Tautomeric forms may be relevant to the attainment of the optimal chemical reactivity and biological activity of a compound of interest.

[0142] As used herein a pure enantiomeric compound is substantially free from other enantiomers or stereoisomers of the compound (i.e., in enantiomeric excess). In other words, an "S" form of the compound is substantially free from the "R" form of the compound and is, thus, in enantiomeric excess of the "R" form. The term "enantiomerically pure" or "pure enantiomer" denotes that the compound comprises more than 75% by weight, more than 80% by weight, more than 85% by weight, more than 90% by weight, more than 91% by weight, more than 92% by weight, more than 93% by weight, more than 94% by weight, more than 95% by weight, more than 96% by weight, more than 97% by weight, more than 98% by weight, more than 98.5% by weight, more than 99% by weight, more than 99.2% by weight, more than 99.5% by weight, more than 99.6% by weight, more than 99.7% by weight, more than 99.8% by weight or more than 99.9% by weight, of the enantiomer. In certain embodiments, the weights are based upon total weight of all enantiomers or stereoisomers of the compound.

[0143] As used herein and unless otherwise indicated, the term "enantiomerically pure R-compound" refers to at least about 80% by weight R-compound and at most about 20% by weight S-compound, at least about 90% by weight R-compound and at most about 10% by weight S-compound, at least about 95% by weight R-compound and at most about 5% by weight S-compound, at least about 99% by weight R-compound and at most about 1% by weight S-compound, at least about 99.9% by weight R-compound or at most about 0.1% by weight S-compound. In certain embodiments, the weights are based upon total weight of compound.

[0144] As used herein and unless otherwise indicated, the term "enantiomerically pure S-compound" or "S-compound" refers to at least about 80% by weight S-compound and at most about 20% by weight R-compound, at least about 90% by weight S-compound and at most about 10% by weight R-compound, at least about 95% by weight S-compound and at most about 5% by weight R-compound, at least about 99% by weight S-compound and at most about 1% by weight R-compound or at least about 99.9% by weight S-compound and at most about 0.1% by weight R-compound. In certain embodiments, the weights are based upon total weight of compound.

[0145] In the compositions provided herein, an enantiomerically pure compound or a pharmaceutically acceptable salt, solvate, hydrate or prodrug thereof can be present with other active or inactive ingredients. For example, a pharmaceutical composition comprising enantiomerically pure R-compound can comprise, for example, about 90% excipient and about 10% enantiomerically pure R-compound. In certain embodiments, the enantiomerically pure R-compound in such compositions can, for example, comprise, at least about 95% by weight R-compound and at most about 5% by weight S-compound, by total weight of the compound. For example, a pharmaceutical composition com-

prising enantiomerically pure S-compound can comprise, for example, about 90% excipient and about 10% enantiomerically pure S-compound. In certain embodiments, the enantiomerically pure S-compound in such compositions can, for example, comprise, at least about 95% by weight S-compound and at most about 5% by weight R-compound, by total weight of the compound. In certain embodiments, the active ingredient can be formulated with little or no excipient or carrier.

[0146] The compounds of this invention may possess one or more asymmetric centers; such compounds can therefore be produced as individual (R)- or (S)-stereoisomers or as mixtures thereof.

[0147] Unless indicated otherwise, the description or naming of a particular compound in the specification and claims is intended to include both individual enantiomers and mixtures, racemic or otherwise, thereof. The methods for the determination of stereochemistry and the separation of stereoisomers are well-known in the art.

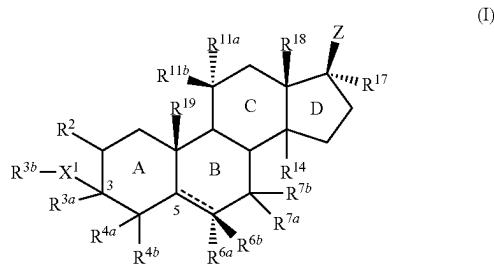

[0148] One having ordinary skill in the art of organic synthesis will recognize that the maximum number of heteroatoms in a stable, chemically feasible heterocyclic ring, whether it is aromatic or non aromatic, is determined by the size of the ring, the degree of unsaturation and the valence of the heteroatoms. In general, a heterocyclic ring may have one to four heteroatoms so long as the heteroaromatic ring is chemically feasible and stable.

Pharmaceutical Compositions

[0317] In another aspect, the invention provides a pharmaceutical composition comprising a pharmaceutically acceptable carrier and a effective amount of a compound of Formula (I).

[0318] When employed as pharmaceuticals, the compounds provided herein are typically administered in the form of a pharmaceutical composition. Such compositions can be prepared in a manner well known in the pharmaceutical art and comprise at least one active compound.

[0319] In one embodiment, with respect to the pharmaceutical composition, the carrier is a parenteral carrier, oral or topical carrier.

[0320] The present invention also relates to a compound of the present invention or pharmaceutical composition thereof for use as a pharmaceutical or a medicament.

[0321] Generally, the compounds provided herein are administered in a therapeutically effective amount. The amount of the compound actually administered will typically be determined by a physician, in the light of the relevant circumstances, including the condition to be treated, the chosen route of administration, the actual compound administered, the age, weight, and response of the individual patient, the severity of the patient's symptoms, and the like.

[0322] The pharmaceutical compositions provided herein can be administered by a variety of routes including oral, rectal, transdermal, subcutaneous, intravenous, intramuscular, and intranasal. Depending on the intended route of delivery, the compounds provided herein are preferably formulated as either injectable or oral compositions or as salves, as lotions or as patches all for transdermal administration.

[0323] The compositions for oral administration can take the form of bulk liquid solutions or suspensions, or bulk powders. More commonly, however, the compositions are presented in unit dosage forms to facilitate accurate dosing.

The term "unit dosage forms" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical excipient. Typical unit dosage forms include prefilled, premeasured ampules or syringes of the liquid compositions or pills, tablets, capsules or the like in the case of solid compositions. In such compositions, the compound is usually a minor component (from about 0.1 to about 50% by weight or preferably from about 1 to about 40% by weight) with the remainder being various vehicles or carriers and processing aids helpful for forming the desired dosing form.

[0324] Liquid forms suitable for oral administration may include a suitable aqueous or nonaqueous vehicle with buffers, suspending and dispensing agents, colorants, flavors and the like. Solid forms may include, for example, any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, or corn starch; a lubricant such as magnesium stearate; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring.

[0325] Injectable compositions are typically based upon injectable sterile saline or phosphate-buffered saline or other injectable carriers known in the art. As before, the active compound in such compositions is typically a minor component, often being from about 0.05 to 10% by weight with the remainder being the injectable carrier and the like.

[0326] Transdermal compositions are typically formulated as a topical ointment or cream containing the active ingredient(s), generally in an amount ranging from about 0.01 to about 20% by weight, preferably from about 0.1 to about 20% by weight, more preferably from about 0.5 to about 15% by weight. When formulated as a ointment, the active ingredients will typically be combined with either a paraffinic or a water-miscible ointment base. Alternatively, the active ingredients may be formulated in a cream with, for example an oil-in-water cream base. Such transdermal formulations are well-known in the art and generally include additional ingredients to enhance the dermal penetration or stability of the active ingredients or the formulation. All such known transdermal formulations and ingredients are included within the scope provided herein.

[0327] The compounds provided herein can also be administered by a transdermal device. Accordingly, transdermal administration can be accomplished using a patch either of the reservoir or porous membrane type, or of a solid matrix variety.

[0328] The above-described components for orally administrable, injectable or topically administrable compositions are merely representative. Other materials as well as processing techniques and the like are set forth in Part 8 of *Remington's Pharmaceutical Sciences*, 17th edition, 1985, Mack Publishing Company, Easton, Pennsylvania, which is incorporated herein by reference.

[0329] The above-described components for orally administrable, injectable, or topically administrable compositions are merely representative. Other materials as well as processing techniques and the like are set forth in Part 8 of *Remington's The Science and Practice of Pharmacy*, 21st

edition, 2005, Publisher: Lippincott Williams & Wilkins, which is incorporated herein by reference.

[0330] The compounds of this invention can also be administered in sustained release forms or from sustained release drug delivery systems. A description of representative sustained release materials can be found in *Remington's Pharmaceutical Sciences*.

[0331] The present invention also relates to the pharmaceutically acceptable formulations of a compound of the present invention. In one embodiment, the formulation comprises water. In another embodiment, the formulation comprises a cyclodextrin derivative. The most common cyclodextrins are α -, β - and γ -cyclodextrins consisting of 6, 7 and 8 α -1,4-linked glucose units, respectively, optionally comprising one or more substituents on the linked sugar moieties, which include, but are not limited to, methylated, hydroxyalkylated, acylated, and sulfoalkylether substitution. In certain embodiments, the cyclodextrin is a sulfoalkyl ether β -cyclodextrin, e.g., for example, sulfobutyl ether β -cyclodextrin, also known as Captisol®. See, e.g., U.S. Pat. No. 5,376,645. In certain embodiments, the formulation comprises hexapropyl- β -cyclodextrin. In a more particular embodiment, the formulation comprises hexapropyl- β -cyclodextrin (10-50% in water).

[0332] The present invention also relates to the pharmaceutically acceptable acid addition salt of a compound of the present invention. The acid which may be used to prepare the pharmaceutically acceptable salt is that which forms a non-toxic acid addition salt, i.e., a salt containing pharmacologically acceptable anions such as the hydrochloride, hydroiodide, hydrobromide, nitrate, sulfate, bisulfate, phosphate, acetate, lactate, citrate, tartrate, succinate, maleate, fumarate, benzoate, para-toluenesulfonate, and the like.

[0333] The following formulation examples illustrate representative pharmaceutical compositions that may be prepared in accordance with this invention. The present invention, however, is not limited to the following pharmaceutical compositions.

[0334] Exemplary Formulation 1—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 240-270 mg tablets (80-90 mg of active compound per tablet) in a tablet press.

[0335] Exemplary Formulation 2—Capsules: A compound of the present invention may be admixed as a dry powder with a starch diluent in an approximate 1:1 weight ratio. The mixture is filled into 250 mg capsules (125 mg of active compound per capsule).

[0336] Exemplary Formulation 3—Liquid: A compound of the present invention (125 mg) may be admixed with sucrose (1.75 g) and xanthan gum (4 mg) and the resultant mixture may be blended, passed through a No. 10 mesh U.S. sieve, and then mixed with a previously made solution of microcrystalline cellulose and sodium carboxymethyl cellulose (11:89, 50 mg) in water. Sodium benzoate (10 mg), flavor, and color are diluted with water and added with stirring. Sufficient water may then be added to produce a total volume of 5 mL.

[0338] Exemplary Formulation 5—Injection: A compound of the present invention may be dissolved or suspended in a buffered sterile saline injectable aqueous medium to a concentration of approximately 5 mg/mL.

[0339] Exemplary Formulation 6—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 90-150 mg tablets (30-50 mg of active compound per tablet) in a tablet press.

[0340] Exemplary Formulation 7—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 30-90 mg tablets (10-30 mg of active compound per tablet) in a tablet press.

[0341] Exemplary Formulation 8—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 0.3-30 mg tablets (0.1-10 mg of active compound per tablet) in a tablet press.

[0342] Exemplary Formulation 9—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 150-240 mg tablets (50-80 mg of active compound per tablet) in a tablet press.

[0343] Exemplary Formulation 10—Tablets: A compound of the present invention may be admixed as a dry powder with a dry gelatin binder in an approximate 1:2 weight ratio. A minor amount of magnesium stearate is added as a lubricant. The mixture is formed into 270-450 mg tablets (90-150 mg of active compound per tablet) in a tablet press.

[0344] Injection dose levels range from about 0.1 mg/kg/hour to at least 10 mg/kg/hour, all for from about 1 to about 120 hours and especially 24 to 96 hours. A preloading bolus of from about 0.1 mg/kg to about 10 mg/kg or more may also be administered to achieve adequate steady state levels. The maximum total dose is not expected to exceed about 2 g/day for a 40 to 80 kg human patient.

[0345] For the prevention and/or treatment of long-term conditions the regimen for treatment usually stretches over many months or years so oral dosing is preferred for patient convenience and tolerance. With oral dosing, one to five and especially two to four and typically three oral doses per day are representative regimens. Using these dosing patterns, each dose provides from about 0.01 to about 20 mg/kg of the compound provided herein, with preferred doses each providing from about 0.1 to about 10 mg/kg, and especially about 1 to about 5 mg/kg.

[0346] Transdermal doses are generally selected to provide similar or lower blood levels than are achieved using injection doses.

[0347] When used to prevent the onset of a CNS-disorder, the compounds provided herein will be administered to a subject at risk for developing the condition, typically on the advice and under the supervision of a physician, at the dosage levels described above. Subjects at risk for developing a particular condition generally include those that have a family history of the condition, or those who have

been identified by genetic testing or screening to be particularly susceptible to developing the condition.

Methods of Treatment and Use

[0348] Earlier studies (see, e.g., Gee et al., *European Journal of Pharmacology*, 136:419-423 (1987)) demonstrated that certain 3 α -hydroxylated steroids are orders of magnitude more potent as modulators of the GRC than others had reported (see, e.g., Majewska et al., *Science* 232:1004-1007 (1986); Harrison et al., *J Pharmacol. Exp. Ther.* 241:346-353 (1987)). Majewska et al. and Harrison et al. taught that 3 α -hydroxylated-5-reduced steroids are only capable of much lower levels of effectiveness. In vitro and in vivo experimental data have now demonstrated that the high potency of these steroids allows them to be therapeutically useful in the modulation of brain excitability via the GRC (see, e.g., Gee et al., *European Journal of Pharmacology*, 136:419-423 (1987); Wieland et al., *Psychopharmacology* 118(1):65-71 (1995)).

[0349] Various synthetic steroids have also been prepared as neuroactive steroids.

[0350] See, for example, U.S. Pat. No. 5,232,917, which discloses neuroactive steroid compounds useful in treating stress, anxiety, insomnia, seizure disorders, and mood disorders, that are amenable to GRC-active agents, such as depression, in a therapeutically beneficial manner. Furthermore, it has been previously demonstrated that these steroids interact at a unique site on the GRC which is distinct from other known sites of interaction (e.g., barbiturates, benzodiazepines, and GABA) where therapeutically beneficial effects on stress, anxiety, sleep, mood disorders and seizure disorders have been previously elicited (see, e.g., Gee, K. W. and Yamamura, H. I., "Benzodiazepines and Barbiturates: Drugs for the Treatment of Anxiety, Insomnia and Seizure Disorders," in Central Nervous System Disorders, Horwell, ed., Marcel-Dekker, New York (1985), pp. 123-147; Lloyd, K. G. and Morselli, P. L., "Psychopharmacology of GABAergic Drugs," in Psychopharmacology: The Third Generation of Progress, H. Y. Meltzer, ed., Raven Press, N.Y. (1987), pp. 183-195; and Gee et al., *European Journal of Pharmacology*, 136:419-423 (1987). These compounds are desirable for their duration, potency and oral activity (along with other forms of administration).

[0351] Accordingly, the compounds and pharmaceutical compositions provided herein find use as therapeutics for preventing and/or treating CNS conditions in mammals including humans and non-human mammals. Thus, and as stated earlier, the present invention includes within its scope, and extends to, the recited methods of treatment, as well as to the compounds for such methods, and to the use of such compounds for the preparation of medicaments useful for such methods. It is contemplated that the novel 3 α - and 3 β -hydroxy steroids of the invention may act as negative allosteric modulators (NAM) of NMDA receptor and thus may be useful for preventing and/or treating a broad range of CNS conditions.

[0352] In one aspect, compounds of the present invention are contemplated as therapeutic agents, e.g., for the treatment of CNS conditions in mammals, such as for the treatment of schizophrenia, depression, bipolar disorder (e.g., I and/or II), schizoaffective disorder, mood disorders, anxiety disorders, personality disorders, psychosis, compulsive disorders, post-traumatic stress disorder (PTSD), Autism spectrum disorder (ASD), dysthymia (mild depres-

sion), social anxiety disorder, obsessive compulsive disorder (OCD), pain (e.g., a painful syndrome or disorder), sleep disorders, memory disorders, dementia, Alzheimer's Disease, a seizure disorder (e.g., epilepsy), traumatic brain injury (TBI), stroke, addictive disorders (e.g., addiction to opiates, cocaine, and/or alcohol), autism, Huntington's Disease, insomnia, Parkinson's disease, withdrawal syndromes, or tinnitus. In certain embodiments, the compounds of the present invention are useful in the treatment of depression, anxiety, mood disorders, sleep disorders, memory disorders, traumatic brain injury, stroke, epilepsy, and schizophrenia.

[0353] In another aspect, provided is a method of treating a mammal susceptible to or afflicted with a condition associated with brain excitability, which method comprises administering an effective amount of one or more of the pharmaceutical compositions described herein.

[0354] In yet another aspect, provided is the use of a compound of the present invention as a pharmaceutical, e.g., especially in the treatment or prevention of the aforementioned conditions and diseases.

[0355] In still yet another aspect, provided is a method of manufacture of a medicament for the treatment or prevention of one of the aforementioned conditions and diseases.

[0356] In still yet another aspect, the present invention provides a method for preventing, treating, ameliorating or managing a disease or condition which comprises administering to a subject in need of such prevention, treatment, amelioration or management, a prophylactically or therapeutically effective amount of a compound of the present invention, or the pharmaceutical composition thereof.

[0357] In yet another aspect, the present invention provides a use of a compound of the present invention for the manufacture of a medicament to treat a disease or condition associated with brain excitability. In one embodiment, the disease or condition is selected from depression, anxiety, schizophrenia, sleep disorders, memory disorders, and mood disorders.

[0358] In yet another aspect, the present invention provides a method of treatment of a mammal, e.g., a human being, to treat a disease associated with brain excitability, including treating said mammal with an effective amount of a compound of the present invention or composition thereof.

[0359] In yet another aspect, the present invention provides a combination of a compound of the present invention and another pharmacologically active agent.

[0360] The compounds provided herein can be administered as the sole active agent or they can be administered in combination with other agents. Administration in combination can proceed by any technique apparent to those of skill in the art including, for example, separate, sequential, concurrent and alternating administration.

EXAMPLES

[0361] In order that the invention described herein may be more fully understood, the following examples are set forth. The synthetic and biological examples described in this application are offered to illustrate the compounds, pharmaceutical compositions and methods provided herein and are not to be construed in any way as limiting their scope.

Materials and Methods

[0362] The compounds provided herein can be prepared from readily available starting materials using the following

general methods and procedures. It will be appreciated that where typical or preferred process conditions (i.e., reaction temperatures, times, mole ratios of reactants, solvents, pressures, etc.) are given, other process conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvent used, but such conditions can be determined by one skilled in the art by routine optimization.

[0363] Additionally, as will be apparent to those skilled in the art, conventional protecting groups may be necessary to prevent certain functional groups from undergoing undesired reactions. The choice of a suitable protecting group for a particular functional group as well as suitable conditions for protection and deprotection are well known in the art. For example, numerous protecting groups, and their introduction and removal, are described in T. W. Greene and P. G. M. Wuts, *Protecting Groups in Organic Synthesis*, Second Edition, Wiley, New York, 1991, and references cited therein.

[0364] The compounds provided herein may be isolated and purified by known standard procedures. Such procedures include (but are not limited to) recrystallization, column chromatography, or HPLC. The following schemes are presented with details as to the preparation of representative substituted biaryl amides that have been listed herein. The compounds provided herein may be prepared from known or commercially available starting materials and reagents by one skilled in the art of organic synthesis.

[0365] The enantiomerically pure compounds provided herein may be prepared according to any techniques known to those of skill in the art. For instance, they may be prepared by chiral or asymmetric synthesis from a suitable optically pure precursor or obtained from a racemate by any conventional technique, for example, by chromatographic resolution using a chiral column, TLC or by the preparation of diastereoisomers, separation thereof and regeneration of the desired enantiomer. See, e.g., "Enantiomers, Racemates and Resolutions," by J. Jacques, A. Collet, and S. H. Wilen, (Wiley-Interscience, New York, 1981); S. H. Wilen, A. Collet, and J. Jacques, *Tetrahedron*, 2725 (1977); E. L. Eliel *Stereochemistry of Carbon Compounds* (McGraw-Hill, NY, 1962); and S. H. Wilen *Tables of Resolving Agents and Optical Resolutions* 268 (E. L. Eliel ed., Univ. of Notre Dame Press, Notre Dame, IN, 1972), *Stereochemistry of Organic Compounds*, Ernest L. Eliel, Samuel H. Wilen and Lewis N. Manda (1994 John Wiley & Sons, Inc.), and *Stereoselective Synthesis A Practical Approach*, Mihály Nográdi (1995 VCH Publishers, Inc., NY, NY).

[0366] In certain embodiments, an enantiomerically pure compound of the present invention may be obtained by reaction of the racemate with a suitable optically active acid or base. Suitable acids or bases include those described in

Bighley et al., 1995, *Salt Forms of Drugs and Adsorption, in Encyclopedia of Pharmaceutical Technology*, vol. 13, Swarbrick & Boylan, eds., Marcel Dekker, New York; ten Hoeve & H. Wynberg, 1985, *Journal of Organic Chemistry* 50:4508-4514; Dale & Mosher, 1973, *J. Am. Chem. Soc.* 95:512; and *CRC Handbook of Optical Resolution via Diastereomeric Salt Formation*, the contents of which are hereby incorporated by reference in their entireties.

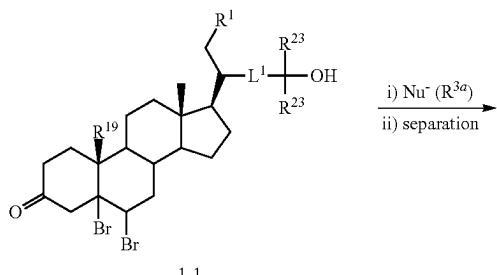

[0367] Enantiomerically pure compounds can also be recovered either from the crystallized diastereomer or from the mother liquor, depending on the solubility properties of the particular acid resolving agent employed and the particular acid enantiomer used. The identity and optical purity of the particular compound so recovered can be determined by polarimetry or other analytical methods known in the art. The diastereoisomers can then be separated, for example, by chromatography or fractional crystallization, and the desired enantiomer regenerated by treatment with an appropriate base or acid. The other enantiomer may be obtained from the racemate in a similar manner or worked up from the liquors of the first separation.

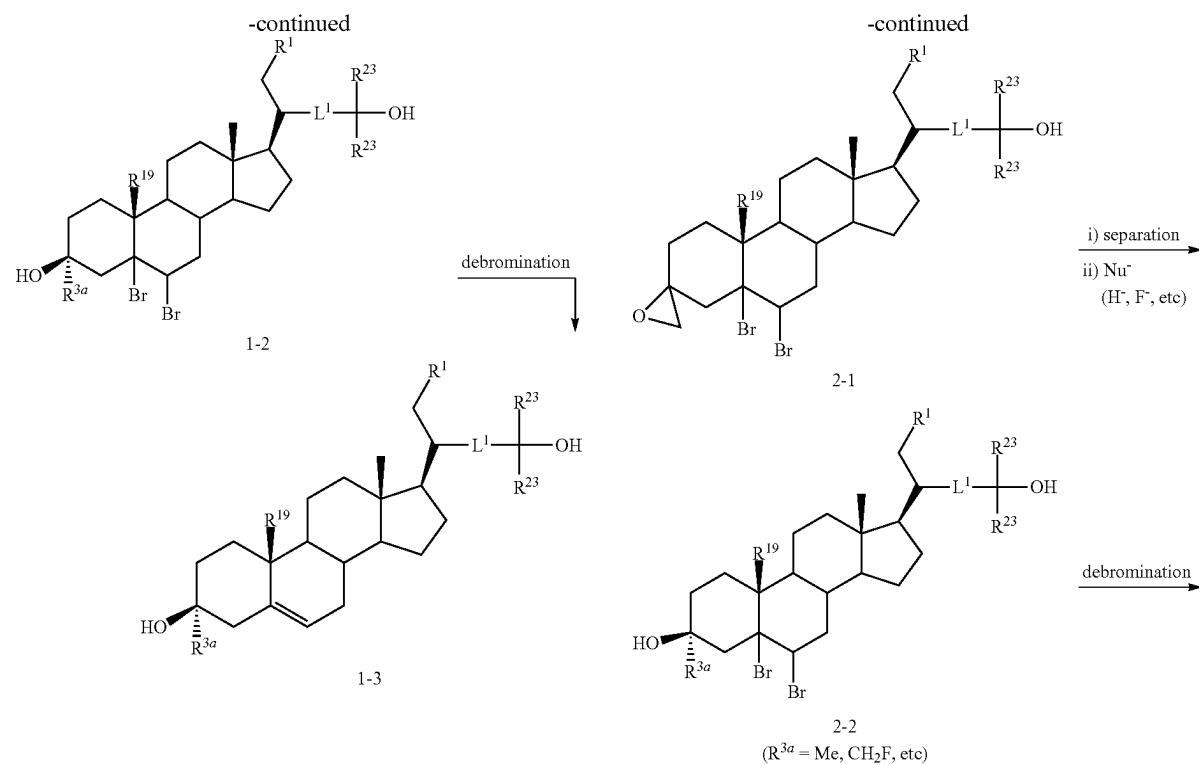

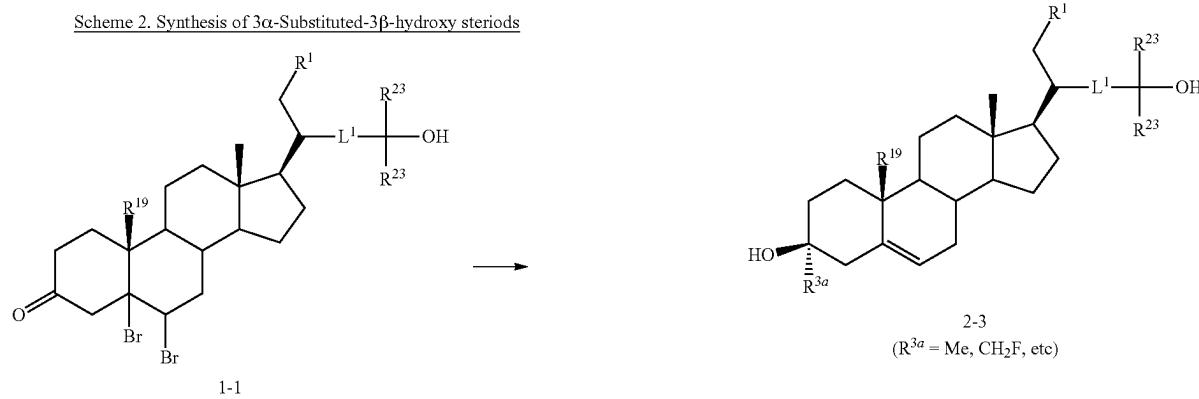

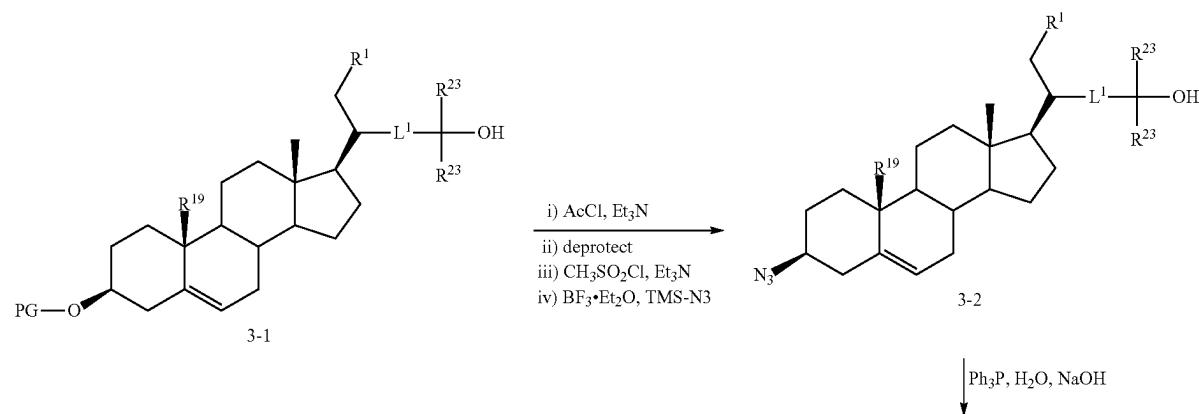

[0368] In certain embodiments, enantiomerically pure compound can be separated from racemic compound by chiral chromatography. Various chiral columns and eluents for use in the separation of the enantiomers are available and suitable conditions for the separation can be empirically determined by methods known to one of skill in the art. Exemplary chiral columns available for use in the separation of the enantiomers provided herein include, but are not limited to, CHIRALCEL® OB, CHIRALCEL® OB-H, CHIRALCEL® OD, CHIRALCEL® OD-H, CHIRALCEL® OF, CHIRALCEL® OG, CHIRALCEL® OJ and CHIRALCEL® OK.

Assay Methods

[0485] Compounds of the present invention can be evaluated using various in vitro and in vivo assays described in the literature; examples of which are described below.

[0486] The following examples are offered to illustrate the biological activity of the compounds, pharmaceutical compositions, and methods provided herein and are not to be construed in any way as limiting the scope thereof.

NMDA Modulation Activity Assay

[0487] The compounds of the invention are or can be tested for their NMDA modulation activity using the assay described by Paul et al., in *J. Pharm. and Exp. Ther.* 1994, 271, 677-682. The assay protocol is reproduced below.

(1) Cell Culture

[0488] Hippocampal neurons from 19-day-old Sprague-Dawley rat embryos are maintained in primary culture, as described previously (Segal, *J. Neurophysiol.* 50 1249-1264, 1983). Briefly, hippocampal tissue is dissected and mechanically disrupted and the cell suspension is plated onto poly-L-lysine (Sigma, St. Louis, MO)-coated, glass-bottom, 35-mm culture dishes that contained modified Eagle's medium with Earle's salts supplemented with 10% fetal bovine serum, 10% horse serum and 2 mM glutamine (Sigma). N₃ serum supplement (modified from Guthrie et al., *Brain Res.* 420 313-323, 1987) consisted of: bovine serum albumin, 0.001%; transferrin, 20 mg/liter; insulin, 10 mg/liter; selenium, 60 nM; corticosterone, 40 g/liter; triiodothyronine, 20 g/liter; progesterone, 40 nM; and putrescine, 200 M, which is added to the media. Cells are incubated in a humidified atmosphere that contained 10% CO₂ and 90% air. Culture media that lacked fetal bovine serum is added every 7 days after plating. The cells are used after 7 to 14 days in culture.

(2) Measurement of Intracellular Ca⁺⁺

[0489] Cultures are washed three times with buffer that contained (in millimolar quantities) the following: NaCl, 145; KCl, 2.5; HEPES, 10; CaCl₂, 1; and glucose, 10 (adjusted to pH 7.4 with NaOH and to an osmolality of 315-325 mOsm with sucrose). The cultures are then incubated with fura-2 acetoxyethyl ester 2 to 5 M for 30 to 45

min in the dark at 37° C. After the incubation period, the cultures are again washed three times with buffer and allowed to stand for >15 min to permit complete hydrolysis of the ester. The neuron of interest is perfused with buffer at a rate of approximately 250 µl/min (37° C.). The perfusion device consisted of a water-jacketed array of 10 tubes that emptied into a common tip positioned approximately 500 µm from the cell. All solutions contained 0.5 M tetrodotoxin to eliminate voltage-sensitive Na⁺ currents and 2 to 5 M glycine to saturate the strychnine-insensitive glycine site on NMDA receptors.

[0490] [Ca⁺⁺] is measured by microspectrofluorimetry with the Ca⁺⁺ sensitive indicator fura-2 (Groden et al., *Cell Calcium* 12: 279-287, 1991). The neurons are illuminated on a Nikon inverted microscope with a dual-wavelength illumination-photometry system (SPEX-DM3000 AR-CM, SPEX Industries, Edison, NJ).

[0491] Excitation of fura-2 occurred at 340 and 380 nm with emitted light monitored at 510 nm. The neurons are visualized by phase-contrast microscopy and are easily identified by their characteristic morphology. Light reaching the photomultiplier is limited to that emitted by the cell of interest by a pinhole. The photon counts are stored in digital form for subsequent analysis. Calibration is carried out as described by Grynkiewicz et al. (*J. Biol. Chem.* 280, 34440-3450, 1985). The fluorescence ratio at saturating Ca⁺⁺ (R_{max}) is determined in situ by bathing the cells in buffer that contained (in millimolar quantities) the following: KCl, 130; NaCl, 17; HEPES, 10; glucose, 10; CaCl₂, 2; and ionomycin, 0.015 (pH 7.2, 37° C. Some calibration buffers contained 10 M carbonyl cyanide-m-chlorophenyl-hydrazone to uncouple mitochondrial oxidative phosphorylation. For the determination of the fluorescence ratio at zero Ca⁺⁺ (R_{min}), the buffer is modified so that 3 mM EGTA and 80 µM EGTA acetoxyethyl ester is substituted for CaCl₂). An apparent K_d of 285 nM (Groden et al., 1991) is used for [Ca⁺⁺]_i calculations.

Electrophysiology Assay

[0492] The compounds of the invention are or can be tested in electrophysiology assay as described by Petrovic et al., in *J. Neuroscience* 160 (2009) 616-628. The assay protocol is reproduced below.

(1) Hippocampal Cultures

[0493] Primary dissociated hippocampal cultures are prepared from 1- to 2-day-old postnatal rats. Animals are decapitated, and the hippocampi are dissected. Trypsin digestion, followed by mechanical dissociation, is used to prepare cell suspension. Single cells are plated at a density of 500,000 cells/cm² on 31- or 12-mm polylysine-coated glass coverslips. Neuronal cultures are maintained in Neurobasal™-A (Invitrogen, Carlsbad, CA, USA) medium supplemented with glutamine (0.5 mM) and B27 Serum-Free Supplement (Invitrogen).

(2) Transfection and Maintenance of HEK293 Cells

[0494] HEK293 cells (American Type Culture Collection, ATTC No. CRL1573, Rockville, MD, USA) are cultured in Opti-MEM® I (Invitrogen) with 5% fetal bovine serum at 37° C. and transfected with NR1-1a/NR2B/green fluorescent protein (GFP) plasmids as described previously (Cais et al., *Neuroscience* 151: 428-438, 2008). Briefly, equal

amounts (0.3 g) of cDNAs coding for NR1, NR2 and GFP (pQBI 25, Takara, Otsu, Shiga, Japan) are mixed with 0.9 µl Matra-A Reagent (IBA, Gottingen, Germany) and added to confluent HEK293 cells on a 24-well plate. After trypsinization, the cells are resuspended in Opti-MEM® I containing 1% fetal bovine serum supplemented with 20 mM MgCl₂, 1 mM D,L-2-amino-5-phosphonopentanoic acid and 3 mM kynurenic acid and plated on 30-mm polylysine-coated glass coverslips. The following genes encoding NMDAR subunits are used: NR1-1a (GenBank accession no. U08261) (Hollmann et al., *Neuron* 10:943-954 1993) and NR2B (GenBank accession no. M91562) (Monyer et al., *Science*, 256: 1217-1221, 1992).

(3) Recording from Cultured Cells and Drug Application
[0495] Experiments are performed 24-48 h after the end of HEK293 transfection; neurons maintained in culture for 5-8 days are used. Whole-cell voltage-clamp recordings are made with a patch-clamp amplifier after a capacitance and series resistance (<10 MΩ) compensation of 80%-90%. Agonist-induced responses are low-pass filtered at 1 kHz with an eight-pole Bessel filter (Frequency Devices, Haverhill, MA, USA), digitally sampled at 5 kHz and analyzed using pCLAMP software version 9 (Axon Instruments). Patch pipettes (3-4 MΩ) pulled from borosilicate glass are filled with Cs⁺ based intracellular solution (Cs-ICS) containing (in mM) 125 gluconic acid, 15 CsCl, 5 EGTA, 10 Hepes, 3 MgCl₂, 0.5 CaCl₂, and 2 ATP-Mg salt (pH-adjusted to 7.2 with CsOH). Extracellular solution (ECS) contained (in mM) 160 NaCl, 2.5 KCl, 10 Hepes, 10 glucose, 0.2 EDTA and 0.7 CaCl₂ (pH-adjusted to 7.3 with NaOH). In some experiments, the concentration of CaCl₂ is lowered to 0.2 mM (with no EDTA) or increased to 2 mM as indicated. Glycine (10 M), an NMDAR coagonist, is present in the control and test solutions. Tetrodotoxin (0.5 M) and bicuculline methochloride (10 M) are used in experiments on cultured hippocampal neurons. The solutions of compounds of invention are made from freshly prepared 20 mM stock in dimethyl sulfoxide (DMSO). The same concentration of DMSO is maintained in all ECSs. A microprocessor-controlled multibarrel fast perfusion system, with a time constant of solution exchange around cells of ~10 ms, is used to apply test and control solutions (Vyklicky et al., *J Physiol Lond* 470:575-600 1990).

[0496] The compounds of the invention are prepared according to synthetic methods described herein and their purity is tested by using conventional methods known to one skilled in the art.

NMDA Binding In Vitro

[0497] Compounds can be screened to determine their potential as modulators of NMDA binding in vitro. These assays are or can be performed in accordance with the above discussed procedures.

In Vivo Pharmacology.

[0498] Male NSA mice weighing between 15-20 g are obtained from Harlan Sprague-Dawley (San Diego, CA). Upon arrival they are housed in standard polycarbonate cages (4 per cage) containing a sterilized bedding material in a room of constant temp (23.0°±2.5° C.) with a 12 h (07.00-19.00 light) light/dark cycle. Food (Teklad LM 485) and water are freely available. Mice are acclimated a minimum of 4 days prior to experimentation.

Hanging Wire Test

[0499] The hanging-wire test used a custom-built apparatus that consisted of a metal wire (2 mm diameter) suspended horizontally above a padded surface (25 cm). Mice are held by the base of the tail, their forepaws placed in contact with the wire, and then released. Animals are required to bring both hindpaws in contact with the wire within 5 sec in order to be scored as a pass. Results are treated quantally.

Drug Metabolism and Pharmacokinetics: HERG Assay

[0500] HEK 293 cells which stably express the HERG potassium channel are used for electrophysiological study. The methodology for stable transfection of this channel in HEK cells can be found elsewhere (Zhou et al., *Biophys. J.* 74:230-41, 1998). Before the day of experimentation, the cells are harvested from culture flasks and plated onto glass coverslips in a standard Minimum Essential Medium (MEM) medium with 10% Fetal Calf Serum (FCS). The plated cells are stored in an incubator at 37° C. maintained in an atmosphere of 95% O₂/5% CO₂. Cells are studied between 15-28 hrs after harvest.

[0501] HERG currents are studied using standard patch clamp techniques in the whole-cell mode. During the experiment the cells are superfused with a standard external solution of the following composition (mM): NaCl, 130; KCl, 4; CaCl₂, 2; MgCl₂, 1; Glucose, 10; HEPES, 5; pH 7.4 with NaOH. Whole-cell recordings are made using a patch clamp amplifier and patch pipettes which have a resistance of 1-3 MΩ when filled with the standard internal solution of the following composition (mM): KCl, 130; MgATP, 5; MgCl₂, 1.0; HEPES, 10; EGTA 5, pH 7.2 with KOH. Only those cells with access resistances below 15 MΩ and seal resistances >1 GΩ are accepted for further experimentation. Series resistance compensation was applied up to a maximum of 80%. No leak subtraction is done. However, acceptable access resistance depended on the size of the recorded currents and the level of series resistance compensation that can safely be used.

[0502] Following the achievement of whole cell configuration and sufficient time for cell dialysis with pipette solution (>5 min), a standard voltage protocol is applied to the cell to evoke membrane currents. The voltage protocol is as follows. The membrane is depolarized from a holding potential of -80 mV to +40 mV for 1000 ms. This was followed by a descending voltage ramp (rate 0.5 mV msec⁻¹) back to the holding potential. The voltage protocol is applied to a cell continuously throughout the experiment every 4 seconds (0.25 Hz). The amplitude of the peak current elicited around -40 mV during the ramp is measured. Once stable evoked current responses are obtained in the external solution, vehicle (0.5% DMSO in the standard external solution) is applied for 10-20 min by a peristaltic pump. Provided there were minimal changes in the amplitude of the evoked current response in the vehicle control condition, the test compound of either 0.3, 1, 3, or 10 mM is applied for a 10 min period. The 10 min period included the time which supplying solution was passing through the tube from solution reservoir to the recording chamber via the pump. Exposing time of cells to the compound solution was more than 5 min after the drug concentration in the chamber well reached the attempting concentration. There is a subsequent wash period of a 10-20 min to assess reversibility.

Finally, the cells are exposed to high dose of dofetilide (5 mM), a specific IKr blocker, to evaluate the insensitive endogenous current.

[0503] All experiments are performed at room temperature ($23\pm1^\circ\text{ C}.$). Evoked membrane currents were recorded on-line on a computer, filtered at 500-1 KHz (Bessel -3 dB) and sampled at 1-2 KHz using the patch clamp amplifier and a specific data analyzing software. Peak current amplitude, which occurred at around -40 mV, is measured off line on the computer.

[0504] The arithmetic mean of the ten values of amplitude is calculated under vehicle control conditions and in the presence of drug. Percent decrease of IN in each experiment was obtained by the normalized current value using the following formula: $\text{IN}=(1-\text{ID}/\text{IC})\times 100$, where ID is the mean current value in the presence of drug and IC is the mean current value under control conditions. Separate experiments are performed for each drug concentration or time-matched control, and arithmetic mean in each experiment is defined as the result of the study.

Drug Metabolism and Pharmacokinetics: Half-Life in Human Liver Microsomes (HLM)

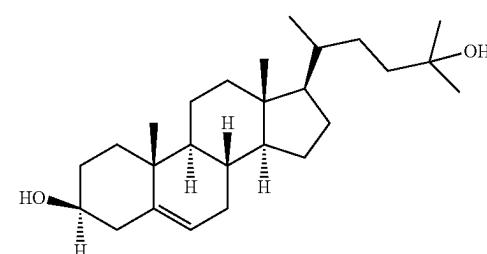

[0505] Test compounds (1 μM) are incubated with 3.3 mM MgCl₂ and 0.78 mg/mL HLM (HL101) in 100 mM potassium phosphate buffer (pH 7.4) at $37^\circ\text{ C}.$ on the 96-deep well plate. The reaction mixture is split into two groups, a non-P450 and a P450 group. NADPH is only added to the reaction mixture of the P450 group. An aliquot of samples of P450 group is collected at 0, 10, 30, and 60 min time point, where 0 min time point indicated the time when NADPH was added into the reaction mixture of P450 group. An aliquot of samples of non-P450 group is collected at -10 and 65 min time point. Collected aliquots are extracted with acetonitrile solution containing an internal standard. The precipitated protein is spun down in centrifuge (2000 rpm, 15 min). The compound concentration in supernatant is measured by LC/MS/MS system. The half-life value is obtained by plotting the natural logarithm of the peak area

ratio of compounds/internal standard versus time. The slope of the line of best fit through the points yields the rate of metabolism (k), and is converted to a half-life value using following equation: $\text{Half-life}=\ln 2/k$.

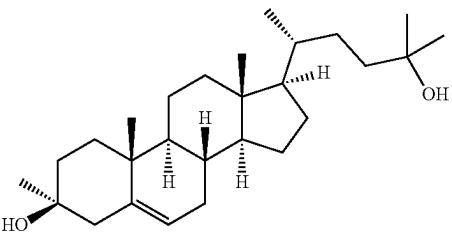

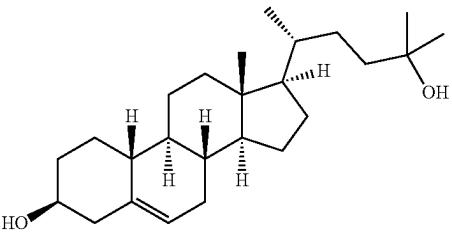

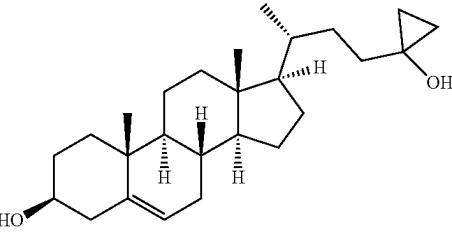

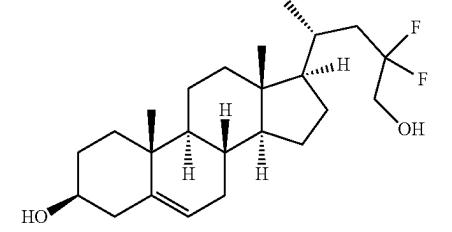

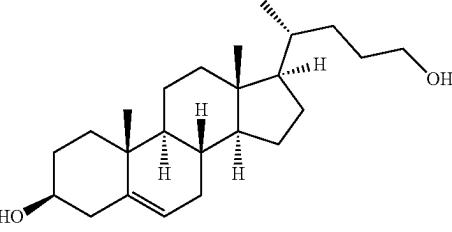

Example 37. NMDA Potentiation Data

[0506] The whole-cell patch-clamp technique was used to investigate the effects of compounds (0.1 mM and 1.0 mM) on the NMDA receptor (GRIN1/GRIN2A subunits) expressed in HEK cells. NMDA/Glycine peak and steady-state currents were recorded from stably transfected cells expressing the NMDA receptor and the modulatory effects of the test items on these currents were investigated.

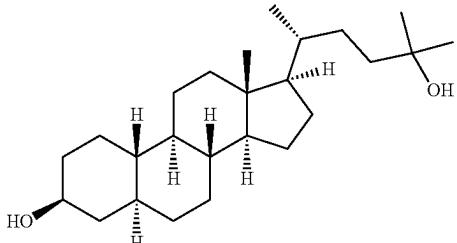

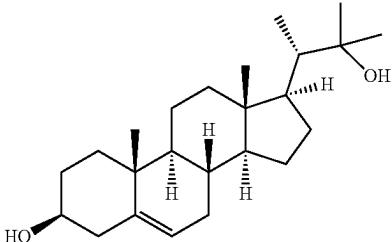

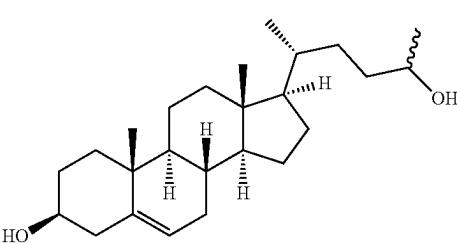

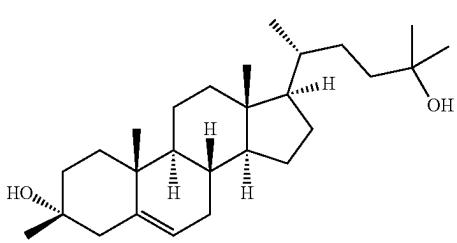

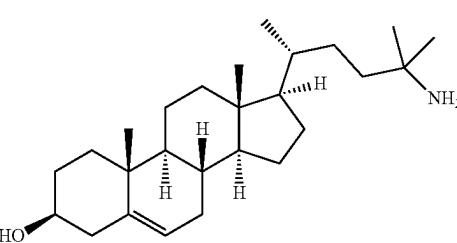

[0507] Cells were stably transfected (LipofectamineTM) with human GRIN1 (variant NR1-3). These cells were transiently transfected with GRIN2A cDNA and CD8 (pLeu) antigenic cDNA. About 24-72 hours following transfection 1 μl Dynabeads M-45 CD8 was added to identify successfully transfected cells (Jurman et al., *Biotechniques* (1994) 17:876-881). Cells were passaged to a confluence of 50-80%. Whole cell currents were measured with HEKA EPC-10 amplifiers using PatchMaster software. Cell culture dishes for recordings were placed on the dish holder of the microscope and continuously perfused (1 ml/min) with bath solution. All solutions applied to cells including the pipette solution were maintained at room temperature ($19^\circ\text{ C}.$ - $30^\circ\text{ C}.$). After formation of a Gigaohm seal between the patch electrodes and transfected individual HEK 293 cells (pipette resistance range: 2.5 MW-6.0 MW; seal resistance range:>1 GW) the cell membrane across the pipette tip was ruptured to assure electrical access to the cell interior (whole-cell patch-configuration). Once a stable seal could be established NMDA inward currents were measured upon application of 30 μM NMDA (and 5.0 μM Glycine) to patch-clamped cells (2 applications) for 5 s. The cells were voltage clamped at a holding potential of -80 mV.
