

US012383194B2

(12) United States Patent Al-Ali et al.

(54) DEPTH OF CONSCIOUSNESS MONITOR

(71) Applicant: Masimo Corporation, Irvine, CA (US)

(72) Inventors: Ammar Al-Ali, San Juan Capistrano, CA (US); Walter M. Weber, Laguna Hills, CA (US); Faisal Kashif, Irvine, CA (US); Mohammad Usman, Mission

Viejo, CA (US); Balaji

Chandrasekaran, Irvine, CA (US)

(73) Assignee: Masimo Corporation, Irvine, CA (US)

(*) Notice: Subject to any disclaimer, the term of this patent is extended or adjusted under 35

U.S.C. 154(b) by 46 days.

(21) Appl. No.: 16/752,303

(22) Filed: Jan. 24, 2020

(65) Prior Publication Data

US 2020/0229729 A1 Jul. 23, 2020

Related U.S. Application Data

(57) ABSTRACT

The present disclosure relates to physiological monitoring to determine the depth of consciousness of a patient under sedation. The monitor includes an EEG sensor and a depth of consciousness monitor. The depth of consciousness monitor can utilize treatment data, such as patient data and/or drug profile information with an EEG signal to determine whether the patient is adequately sedated.

DEPTH OF CONSCIOUSNESS MONITOR

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a divisional of U.S. application Ser. No. 13/911,939, filed Jun. 6, 2013, now U.S. Pat. No. 10,542,903, which claims the benefit of priority from U.S. Provisional No. 61/703,747, filed Sep. 20, 2012, and U.S. Provisional No. 61/656,974, filed Jun. 7, 2012, all of which ¹⁰ are incorporated by reference in their entireties.

FIELD OF THE DISCLOSURE

The present disclosure relates to the field of patient 15 monitoring. In some embodiments, the disclosure relates to monitoring the depth of consciousness of a patient under anesthetic sedation.

BACKGROUND

General anesthesia is often used to put patients to sleep and block pain and memory during medical or diagnostic procedures. While extremely useful, general anesthesia is not risk free. Caregivers therefore generally seek to maintain 25 a depth of consciousness consistent with the needs of a particular medical procedure. Caregivers will monitor various physiological parameters of the patient to predict the patient's depth of consciousness. In response to monitored parameters, the caregiver may manually adjust the anes- 30 thetic dosage level to avoid over and under dosing. However, as a patient's depth of consciousness may frequently change, caregivers often employ a host of monitoring technologies to attempt to periodically, sporadically, or continually ascertain the wellness and consciousness of a patient. 35 For example, caregivers may desire to monitor one or more of a patient's temperature, electroencephalogram or EEG, brain oxygen saturation, stimulus response, electromyography or EMG, respiration, body oxygen saturation or other blood analytes, pulse, hydration, blood pressure, perfusion, 40 or other parameters or combinations of parameters. For many of the foregoing, monitoring technologies are individually readily available and widely used, such as, for example, pulse oximeters, vital signs monitors, and the like.

In their depth of consciousness monitoring, caregivers 45 may also use recording devices to acquire EEG signals. For example, caregivers place electrodes on the skin of the forehead to detect electrical activity produced by the firing of neurons within the brain. From patterns in the electrical activity, caregivers attempt to determine, among other 50 things, the state of consciousness of the brain. Caregivers may also use a pulse oximeter or cerebral oximetry to determine the percentage of oxygenation of the hemoglobin in the patient's blood. Caregivers may also use an EMG monitor to detect the muscular action and mechanical 55 impulses generated by the musculature around the patient's forehead, among other bodily locations. Caregivers manually monitor such physiological parameters and then manually adjust anesthetic dosage.

However, manual monitoring and dosage adjustment 60 could lead to serious adverse results, including death, if improperly performed. In addition, typical depth of consciousness monitors do not account for variations in responses to sedation therapies that exist between patient demographics. Furthermore, typical depth of consciousness 65 monitors do not account for differences in physiological responses that exists between particular sedation therapies

2

and among different patient populations. Therefore, there remains a need in the art for a depth of consciousness monitor that is configured to automatically communicate with a caregiver and/or an anesthetic dosage device to provide accurate control over patient care by accounting for variations between populations and drug actions.

SUMMARY

Based on at least the foregoing, the present disclosure seeks to overcome some or all of the drawbacks discussed above and provide additional advantages over prior technologies. The present disclosure describes embodiments of noninvasive methods, devices, and systems for monitoring depth of consciousness through brain electrical activity.

In one embodiment, a depth of consciousness monitor is configured to determine the level of sedation of a medical patient. The depth of consciousness monitor includes: an EEG interface configured to receive an EEG signal from an EEG sensor; an EEG front end configured to pre-process the EEG signal; a processor, configured to determine a level of sedation of a medical patient based at least upon the pre-processed EEG signal, wherein the processor is further configured to determine delay information associated with the time the EEG signal is received and the time the level of sedation is determined; and a drug delivery device interface, configured to provide the level of sedation and the delay information to a drug delivery device.

In some embodiments the EEG front end includes an EEG engine and an EMG engine configured to extract EEG information and EMG information from the EEG signal, respectively. In some embodiments, the processor is further configured to time stamp the EEG signal when received from the EEG sensor. In one embodiment, the depth of consciousness monitor also includes an additional sensor front end, such as an SpO2 sensor front end. In some embodiments, the depth of consciousness monitor also includes a data port configured to receive at least one of patient data and drug profile information. The processor may be configured to determine a level of sedation of a medical patient based at least upon the pre-processed EEG signal and the at least one of patient data and drug profile information. In some embodiments, the depth of consciousness monitor also includes the EEG sensor and/or the drug delivery system. In some embodiments, the drug delivery device interface includes a wireless communication device.

In another embodiment, a depth of consciousness monitor is configured to determine the level of sedation of a medical patient. The depth of consciousness monitor includes: an EEG interface configured to receive an EEG signal from an EEG sensor; an EEG front end configured to pre-process the EEG signal; a processor, configured to determine a level of sedation of a medical patient based at least upon the pre-processed EEG signal, and a data port configured to transmit the patient sedation level. The processor can include: two or more computing engines, each configured to compute a possible sedation level according to a different process; and a decision logic module, configured to determine the patient's sedation level based at least upon the possible sedation level computations;

In some embodiments, at least one of the computing engines is configured to implement a motion vector process, a phase coherence process, and/or utilize a brain model to compute one of the possible sedation levels. The EEG front end may include an EEG engine and an EMG engine configured to extract EEG information and EMG informa-

tion from the EEG signal, respectively. In some embodiments, the data port comprises a display and/or a wireless communication device.

In yet another embodiment, a method of determining the level of sedation of a medical patient is provided. The method includes: receiving an EEG signal indicative of a medical patient's EEG; receiving treatment data associated with at least one of the medical patient and a drug to be delivered to the medical patient; and determining a level of sedation based at least upon the EEG signal and the treatment data.

In some embodiments, the treatment data includes at least one of a patient age, age classification, sex, weight, bodymass index, a physiological parameters, a temperature, a blood oxygen concentration, an EMG signal, a drug type, a drug class, a mechanism of delivery, and an active ingredient. In some embodiments, determining a level of sedation comprises determining two or more possible levels of sedation with parallel computing engines and wherein said 20 determining the level of sedation of the medical patient is based upon said possible levels of sedation. In some embodiments, determining the level of sedation comprises averaging two or more possible levels of sedation and/or selecting one of the possible levels of sedation as the level of sedation 25 of the medical patient. In some embodiments, determining the possible levels of sedation is performed with motion vector analysis, phase coherence, and or by utilizing a brain model.

For purposes of summarizing the disclosure, certain ³⁰ aspects, advantages and novel features of the disclosure have been described herein. Of course, it is to be understood that not necessarily all such aspects, advantages or features will be embodied in any particular embodiment of the disclosure.

BRIEF DESCRIPTION OF THE DRAWINGS

The following drawings and the associated descriptions are provided to illustrate embodiments of the present disclosure and do not limit the scope of the claims.

- FIG. 1 illustrates an embodiment of a depth of consciousness monitoring system under closed-loop control.
- FIG. 2 illustrates a block diagram of one embodiment of the depth of consciousness monitor of FIG. 1.
- FIG. 3 illustrates one embodiment of the forehead sensor 45 of FIG. 1.
- FIG. 4 illustrates one embodiment of an EEG frequency spectrum of the patient before and during sedation using the depth of consciousness monitor of FIG. 2.
- FIG. 5 illustrates one embodiment of the processor of the 50 depth of consciousness monitor of FIG. 2.
- FIG. 6 illustrates another embodiment of the processor of the depth of consciousness monitor of FIG. 2.
- FIG. 7 illustrates yet another embodiment of the processor of the depth of consciousness monitor of FIG. 2.
- FIG. 8 illustrates one embodiment of a routine to determine patient sedation information that can be performed by any of the processors of FIGS. 5-7.
- FIG. 9 illustrates another embodiment of a routine to determine patient sedation information that can be performed by any of the processors of FIGS. 5-7.
- FIG. 10 illustrates another embodiment of a depth of consciousness monitoring system.
- FIG. 11 illustrates one embodiment of the depth of consciousness monitoring system of FIG. 10.
- FIG. 12 illustrates one embodiment of the depth of consciousness monitoring assembly of FIG. 10.

FIG. 13 illustrates the depth of consciousness monitoring assembly of FIG. 12 attached to a sensor assembly.

FIGS. **14-16** illustrate views of the display of a multiparameter monitor displaying physiological signals received from the depth of consciousness monitor of FIG. **10**.

DETAILED DESCRIPTION

The present disclosure generally relates to patient moni-10 toring devices. In order to provide a complete and accurate assessment of the state of a patient's various physiological systems, in an embodiment, a sensor may advantageously monitor one, multiple or combinations of EEG, EMG, cerebral oximetry, temperature, pulse oximetry, respiration, and other physiological parameters. In various embodiments, the sensor includes a disposable portion and reusable portion. For example, the disposable portion may advantageously include components near a measurement site surface (the patient's skin), including, for example, an EEG sensor, an EMG sensor, a temperature sensor, tape, adhesive elements, positioning elements, or the like. In addition, or alternatively, the reusable portion may advantageously include other components, circuitry or electronics, which, in some embodiments include time-of-use restrictions for quality control or the like. The reusable portion, can be used multiple times for a single patient, across different patients, or the like, often depending upon the effectiveness of sterilization procedures. The reusable components may include, for example, cerebral oximetry components, pulse oximetry components and other components to measure other various parameters.

In an embodiment, the disposable portion of the sensor may include an inductance connection or other electrical connection to the reusable portion of the sensor. The physiological signals from all sensors can be transmitted through a common cable to a depth of consciousness monitor. In an embodiment, the depth of consciousness monitor may include an analog to digital converter, various electrical filters, and a microcontroller for processing and controlling the various sensor components.

In an embodiment, a depth of consciousness monitor is configured to communicate with the forehead sensor and one or more host display and patient monitoring stations. In an embodiment, the patient monitoring station may be a pulse oximeter. In an embodiment, the pulse oximeter may perform integrated display, data monitoring and processing of patient parameters including a connection for power and data communication. In an embodiment, some or all communication may be through wired, wireless, or other electrical connections. In an embodiment, the depth of consciousness monitor may advantageously be housed in a portable housing. In such embodiments, the unit may advantageously be physically associated with a monitored patient, such as, for example, attached in an arm band, a patient bed pouch, a hood or hat, a pocket of a shirt, gown, or other clothing, or the like. In other embodiments, the unit may be entirely or partially housed in a cable connector. In an embodiment, the signal processing and condition unit and/or the depth of consciousness monitor could also monitor patient parameters through other sensors including, for example, ECG, Sp02 from the earlobe, finger, forehead or other locations, blood pressure, respiration through acoustic or other monitoring technologies, or other clinically relevant physiological parameters.

In an embodiment, the depth of consciousness monitor communicates with a sensor, such as a forehead sensor including one or more light sources configured to emit light

at a patient's forehead. In an embodiment, the light source may include one or more emitters or emitter systems, such emitters or emitter systems may be embedded into a substrate. In various embodiments, the emitters could include light emitting diodes ("LEDs"), lasers, superluminescent 5 LEDs or some other light emitting components. These components could be arranged in any pattern on the substrate and could be either a single light emitting source or several light emitting sources. In an embodiment, the emitting components could emit light that deflects off of reflective surfaces associated with a cap of the substrate. The reflective cover could be any number of shapes or sizes and could be constructed to direct light to specific points or a point on the cap or substrate.

In an embodiment, a multi-faceted splitting mirror could 15 reflect light to an opening in the substrate that would allow the light to escape and be emitted to an emission detector in an embodiment also housed in the light source substrate. The emission detector may advantageously sample the light providing feedback usable to create an optical bench or at 20 least optical bench properties of the light source, including, for example, determinations of intensity, wavelength, or the like. In an embodiment, the light source may include a polarized filter for adjusting the emitter light, in some embodiments before exiting an opening in the emitter or 25 being detected by the emission detector.

In an embodiment, a caregiver could analyze physiological information collected from the various sensors including a patient's temperature, EEG, brain oxygen saturation, stimulus response, electromyography or EMG, respiration 30 using acoustic sensor applied to the through, body oxygen saturation, glucose concentration, or other blood analytes, pulse, hydration, blood pressure, perfusion, or other parameters or combinations of parameters to determine relevant information about the state of a patient's well-being. In 35 another embodiment, a caregiver may advantageously analyze information collected from the various sensors to more completely assess the overall depth of a patient's sedation and obtain an assessment superior to an assessment derived from monitoring a single or a few of the parameters men-40 tioned above.

Reference will now be made to the Figures to discuss embodiments of the present disclosure.

FIG. 1 illustrates one example of a depth of consciousness monitoring system 100. In certain embodiments, the depth 45 of consciousness monitoring system 100 measures one or more physiological parameters including cerebral electrical activity (e.g., via EEG), cerebral muscular activity (e.g., via EMG), temperature, cerebral oxygenation, including venous and arterial oxygenation, arterial oxygenation at various 50 other points on the body, various other blood analytes, including total hemoglobin, glucose, lipids, stimulus response, electromyography or EMG, respiration, pulse, hydration, blood pressure, perfusion, or other parameters or combination of other physiologically relevant patient characteristics. The information from these physiological parameters can be evaluated using trend analysis, absolute and relative measures of certain parameters, combined or alone to evaluate the total wellness and current state of sedation of a patient.

The depth of consciousness monitoring system 100 includes multiple or a single sensor 120 in communication with a depth of consciousness monitor 140 via a communications link 150. In the illustrated embodiment, the depth of consciousness monitoring system 100 also includes a 65 drug delivery device 160 that receives a control signal from the depth of consciousness monitor 140 via a control link

6

170. The drug delivery device 160 provides one or more sedatives (e.g., narcotic, hypnotic, analgesic, opiate, etc.) to a patient 180 via a conduit 190.

The sensor 120 can include any variety of shapes and sizes, and could be applied to a variety of measurement sites on a patient's skin including any location on the forehead and temples or other location of the head. One example of a sensor 120 configured for placement on a patient's forehead is described below with respect to FIG. 3. The sensor 120 generally includes one or more electrodes and is configured to measure the electrical activity within the patient's head and generate an EEG signal, as discussed in further detail below.

In some embodiments, the sensor's electrodes are designed to be placed at a measurement site covered with a patient's hair. A caregiver or patient may fasten the sensor to the patient's head with a variety of mechanism including adhesive, straps, caps, combinations of the same, or other devices for fastening sensors to a patient's body or skin known in the art.

In some embodiments, the communication link 150 and/ or the control link 170 are wired electrical connections (e.g., an electrical cable, etc.). In other embodiments, the communication link 150 and/or the control link 170 utilize wireless communication to provide portability, and greater flexibility in depth of consciousness monitor placement with respect to the drug delivery device 160. Wireless communications also help accommodate an ambulatory patient, or other patient in transit. For example, in one embodiment, the depth of consciousness monitor 140 may be attached to an arm band or included in an arm band or other device that is wearable by the patient, including in a cap, a hood, a sling or a pocket of a garment. In such an embodiment, the sensor 120 communicates with the arm band depth of consciousness monitor 140 via a wired or a wireless connection.

In an embodiment, the depth of consciousness monitor 140 communicates wirelessly with the drug delivery device 160 over a wireless control link 170. This allows the depth of consciousness monitor 140 to be transported between various caregiving facilities, each with their own stationary drug delivery devices 160 without unhooking and reinserting hardwired electrical connections. Instead, the depth of consciousness monitor 140 could establish a wireless communication link with a stationary drug delivery device 160 as the depth of consciousness monitor 140 is brought into proximity with the drug delivery device 160. In an embodiment, the devices could establish the connection automatically and patient data may be automatically sent from the depth of consciousness monitor 140 to the drug delivery device 160. In other embodiments, caregiver interaction is required to establish a wireless control link 170 between the depth of consciousness monitor 140 and the drug delivery device 160. Such configurations advantageously facilitate portability and seamless monitoring of a patient while the patient is transported, for example, from an ambulance to a hospital room or from room to room within a hospital.

In an embodiment, the depth of consciousness monitor 140 also communicates with, or incorporates, a pulse oximeter (not shown). The pulse oximeter may be a multifor parameter monitor or other host device capable of monitoring a wide variety of vital signs and blood constituents and other parameters or combinations of parameters such as those monitors commercially available from Masimo Corporation of Irvine, CA, and disclosed herein with reference to U.S. Pat. Nos. 6,584,336, 6,661,161, 6,850,788, and 7,415,297, among others assigned to Masimo Corporation, and U.S. Patent Publication No. 2006/0211924, 2010/

0030040, among others assigned to Masimo Corporation or Masimo Laboratories, Inc. of Irvine CA, all of which are incorporated by reference in their entireties.

The communication link **150** and the control link **170** can include any of a variety of wired or wireless configurations. 5 For example, in some embodiments the links **150**, **170** are implemented according to one or more of an IEEE 801.11x standard (e.g., a/b/g/n, etc.), a BLUETOOTH wireless standard, and a wireless medical information communications standard, etc.

The drug delivery device 160 generally includes at least a drug therapy interface 192, a drug flow device 194, and a flow controller 196. The drug therapy interface 192 receives a drug and provides a flow path to the drug flow device 194. For example, the drug therapy interface 192 can include a 15 port or receptacle to receive or interface with a drug capsule, intravenous bag, syringe, etc. The drug flow device 194 receives the drug therapy from the drug therapy interface 192 and allows the drug to flow to the patient 180 via the conduit 190. In some embodiments, the drug flow device 20 194 includes one or more of a solenoid, a pump, a valve, a peristaltic pump, a variable speed pump, a compression sleeve (e.g., to squeeze an intravenous bag), etc. The action and activation of the drug flow device 194 is controlled by the flow controller 196. The flow controller 196 includes a 25 microcontroller, a memory, a signal input to receive a control signal from the depth of consciousness monitor 140 via the control link 170 and a signal output to provide control over the functionality of the drug flow device 194. The signal input can include a wireless radio to facilitate 30 wireless communication over a wireless control link 170. The signal input allows closed-loop control over the operation of the drug delivery device 160, as will be described in greater detail below.

In some embodiments, the drug delivery device **160** is 35 manually controlled by a clinician (e.g., an anesthesiologist) and/or includes a manual override to allow the clinician to take control over drug delivery to the patient **180**. Therefore, in some embodiments, the depth of consciousness monitoring system **100** does not include an electronic control link 40 **170** between the depth of consciousness monitor **140** and the drug delivery device. Instead, in such an open-loop configuration, the depth of consciousness monitor **140** displays an indication of the patient's depth of consciousness. The clinician is able to manually adjust drug therapy to the 45 patient in response to the signals displayed by the depth of consciousness monitor **140**.

In some embodiments, the depth of consciousness monitor 140 is configured to generate and/or provide a delay signal (which is a form of delay information) to the drug 50 delivery device 160. The delay signal may be used by the drug delivery device to control whether the depth of consciousness monitoring system 100 is operating under positive or negative feedback. In some embodiments, the drug delivery device 160 controls or delays the delivery of drugs 55 provided to the patient 180 in response to the delay signal. For example, the drug delivery device 160 may delay drug deliver to make sure that the depth of consciousness monitoring system 100 is operating under negative feedback, and is therefore a stable control system.

The delay signal can be determined by the depth of consciousness monitor 140 in any of a variety of manners. In one embodiment, the depth of consciousness monitor 140 time stamps the data received from the sensor 120 and provides the time stamp information or other related time 65 information to the drug delivery device 160 as the delay signal. For example, in some embodiments, the delay signal

8

includes the time stamp associated with the data received from the sensor 120 as well as a time stamp associated with the time the control signal data packet is sent to the drug delivery device 160. In other embodiments, the delay signal includes the difference between the two time stamps. In some embodiments, the drug delivery device 160 is configured to calculate or otherwise determine the appropriate control delay based upon the delay signal. For example, the drug delivery device 160 may time stamp the time the control signal is received from the depth of consciousness monitor 140. The drug delivery device 160 can determine a control delay based upon the difference between the time the control signal is received from the depth of consciousness monitor 140 and the time the depth of consciousness monitor received the signal from the sensor 120 that was used to generate the associated data packet received by the drug delivery device. The signal propagation delay through the depth of consciousness monitoring system 100 may be used to keep the system's feedback negative to avoid oscillation and to achieve stability.

In an embodiment, a caregiver or the patient may attach the depth of consciousness monitor 140 directly to the patient's arm or other part or clothing of the patient through an armband with straps or some other means known in the art to connect a portable monitoring unit to a patient. In an embodiment, a depth of consciousness monitor 140 may be integrated into a hat or other headgear wearable by the patient or some other structure near the patient. In an embodiment, the depth of consciousness monitor 140 can rest on a table or other surface near the patient.

In some embodiments, a depth of consciousness monitor 140 is integrated with the drug delivery device 160. Alternatively, the depth of consciousness monitor 140 could be a module that is docked or otherwise attached to the drug delivery device 160. The depth of consciousness monitor 140 can communicate with and/or be integrated with a variety of other device, such as a pulse oximeter, a respiration monitor, and EKG device, a blood pressure measurement device, a respirator, and/or a multi-parameter monitor.

FIG. 2 illustrates a block diagram of one embodiment of the depth of consciousness monitor 140, sensors 120, and drug delivery device 160. In an embodiment, the depth of consciousness monitor 140 includes a processor 220 which may be a micro-controller or other processor, to control and/or process signals received from the sensors 120. For example, the processor 220 may coordinate, process or condition, or manipulate the signals received from the sensor 120 to generate electronic data, control signals, and/or delay signals that are subsequently displayed and/or communicated to the drug delivery device 160. In addition, the processor 220 may receive instructions or data control messages from the drug delivery device 160 or other patient monitoring device to provide the appropriate conditioning and controlling of the various front end components of the sensors 120. Data transmitted between the depth of consciousness monitor 140, the drug delivery device 160, the sensors 120 and any other associated components, devices, or systems in communication with the depth of consciousness monitoring system 100 may be communicated by the devices using one or more interfaces, e.g., electrical wires, wireless communication, optical communication, RFID, LAN networks, or other electronic devices for communicating data known in the art. In one embodiment, a drug delivery device interface can include any one or more of electrical wires, wireless communication, optical communication, RFID, LAN networks, or other electronic devices for communicating data known in the art. In one embodiment,

a multi-parameter physiological monitor interface can include any one or more of electrical wires, wireless communication, optical communication, RFID, LAN networks, or other electronic devices for communicating data known in the art.

The depth of consciousness monitor 140 may also include various front end components to enable the depth of consciousness monitor 140 to process the various signals received by the various sensors 120 that may be communicating with the depth of consciousness monitor 140. In an embodiment, front end components may translate and transmit instructions and control signals for driving the various sensors. In an embodiment, the front end components may translate, process, or transmit instructions and control signals to the emitting or light producing components of the sensor. The front end components may also receive and transmit data acquired by the detectors of the sensors to the microcontroller 220 or other processor 220. The front end components can include one or more of an analog-to-digital 20 converter, a preamplifier, an amplifier, a filter, a decimation filter, a demodulator, etc.

These front end components could include front end components for a variety of sensors 120 including for sensors that detect blood oxygenation, EEG, EMG, ECG, 25 temperature, acoustic respiration monitoring ("ARM") sensors, such as those available from Masimo Corporation of Irvine, CA, acoustic throat respiratory sensor, and brain oxygenation. In an embodiment, a caregiver could advantageously utilize a device with the ability to monitor the 30 plurality of above mentioned parameters to more accurately determine a depth of a patient's sedation. However, in some embodiments, the depth of consciousness monitor 140 only includes EEG and EMG front end components. In an embodiment, a front end component that would be associ- 35 ated with a sensor 120 that detects brain oxygenation may have a sub component dedicated to driving emitters 230 associated with a light source of the brain oxygenation sensor and a sub-component associated with the detector 230 or detectors 230 of the brain oxygenation sensor 300 for 40 receiving and transmitting the detected signals that pass through various body tissues. In other embodiments, the light drivers and detector front end are omitted.

In an embodiment, one of the various sensors associated with the front end components of the brain oximetry unit 45 could be, for example, a blood oxygenation sensor **310** which may be placed at various measurement sites on a patient's skin, including the earlobe, finger, forehead or other places known in the art suitable for detecting blood oxygenation. Many suitable pulse oximeter sensors **310** are 50 known in the art such as those blood oxygenation sensors **310** commercially available from Masimo Corporation of Irvine, CA, including but not limited to those described in U.S. Pat. Nos. 5,638,818, 6,285,896, 6,377,829, 6,580,086, 6,985,764, and 7,341,559, which are expressly incorporated 55 by reference in their entireties.

In an embodiment, a temperature sensor 320 communicates with an associated front end component of the depth of consciousness monitor 140. The temperature sensor 320 detects the temperature of the skin, the temperature inside 60 the ear, the temperature under the tongue, or any other temperature measurement method known in the art. In an embodiment, the temperature sensor 320 could be any suitable thermistor, or any other temperature sensor 320 known in the art capable of detecting a surface temperature 65 of a patient's skin. Additional temperature sensor may advantageously provide feedback to the depth of conscious-

10

ness monitor 140 regarding the performance or temperature of one, combinations of, or all of the emitters 230.

An EEG sensor 330 may also be associated with the front end components of the depth of consciousness monitor 140. In an embodiment, the EEG sensor 330 may be any of a variety of EEG sensors 330 known in the art. An EEG sensor 330 could be applied to a patient at any of a multitude of locations and measurement sites on the skin of the head of a patient. In an embodiment, the EEG sensor 330 may include electrode leads that may be placed on a measurement site in contact with the skin of the patient. In an embodiment, the EEG 330 may monitor the electrical activity of a patient's brain through any number of electrodes, electrode leads, and channels or other systems known in the art. One such EEG sensor 330 is illustrated in FIG. 3 and described in greater detail below.

In an embodiment, the EEG sensor **330** may monitor and collect data from a patient's brain using 4 channels and 6 electrodes. In another embodiment, the EEG **330** may use 3 channels and 5 electrodes. In another embodiment, any variety or combination of sensors maybe be used that are suitable for obtaining an EEG signal, such as those described in U.S. Pat. Nos. 60/164,444, 6,654,626, 6,128,521, which are incorporated by reference in their entireties.

A brain oxygenation sensor 300 may also be associated with the front end components of the depth of consciousness monitor 140. In an embodiment, the brain oxygenation sensor 300 includes a light source 230, and a detector 260. The light source 230 of the brain oxygenation sensor 300 includes emitter(s) that would emit light, sonic or other radiation into the forehead at one, two or other plurality of measurement sites located on the skin of the patient at a plurality of predetermined wavelengths. In an embodiment, the brain oxygenation sensor 300 would include a detector **260** with photodiodes or other radiation detection devices to detect the radiation emitting from the patient at a one or two or a plurality of measurement sites on the skin of the head of a patient. Many suitable brain oxygenation sensors 300 and cerebral oximeters are known in the art including those disclosed in U.S. Pat. Nos. 7,072,701, 7,047,054, which are expressly incorporated by reference in their entireties.

In an embodiment, the light source 230 of the brain oxygenation sensor 300 may include an emission detector 260. In an embodiment, the emission detector 260 detects the light emitted from the light source 230 before passing through or contacting the measurement site of the patient. In an embodiment, an output from the emission detector 230 would be communicated to the micro-controller 220 of the depth of consciousness monitor 140 in order to calculate an approximate output intensity of the light emitted by the emitter(s) 230. The micro-controller 220 or other processor 220 could calculate the output intensity based on the output of the emission detector 260 by comparing the data to calibration data. In an embodiment, the calibration data could include measurement of intensity of light emitted from the emitter(s) 230 and corresponding measurements of output from the emission detector 260. This data could then be correlated to real time output from the emission detector 260 while the oxygenation sensor 230 is in use to determine an actual or approximate intensity of light or radiation being emitted by the emitter(s) 230 utilizing a calibration curve or other suitable calculation or processing method. In an embodiment, the calibration data may be stored in an EPROM or other memory module in the depth of consciousness monitor 140 or other patient processing module or device associated with the patient monitoring system 100.

In an embodiment, the detector 260 detects light or other radiation emitted from the light source 230 after, in an embodiment, some of the light has entered the measurement site on the patient and has been attenuated by a patient's tissue. In an embodiment, the detector 260 could be any number of detectors known in the art for detecting light or other radiation including photodiodes or other types of light or radiation detectors. In one embodiment, the detector 260 may convert detected light or other radiation into a signal, for example, an electrical output signal, which may repre- 10 sent the intensity or other attributes of the radiation. In an embodiment, the signal from the detector 260 may be sent to a brain oxygenation detector 260 front end located in the depth of consciousness monitor 140 for processing, conditioning or transmitting to a pulse oximeter (not shown) or 15 other patient monitoring processor. In one embodiment, the signal may be converted into a digital format by an analog to digital converted located in the depth of consciousness monitor 140. In an embodiment, the data from the detector 260 of the brain oxygenation sensor 300 may be processed 20 to determine the cerebral oxygenation of a patient's brain tissue. In an embodiment, the processing of the data may include determining the changes of intensity between various wavelengths of emitted and detected light of the cerebral oxygenation sensor 300.

In an embodiment, a cerebral oximeter or multi-parameter monitor (not shown) acquires data from the depth of consciousness monitor **140** or sensor **120** derived from physiologically relevant parameters. In an embodiment, the pulse oximeter could provide visual quantitative or qualitative 30 assessments of the patient's well-being based on one or more of the various parameters or physiological attributes measured.

In an embodiment, a caregiver may utilize various physiological parameters to make a quantitative assessment of the 35 patient's depth of sedation as indicated by an index based on for example, a patient's temperature, electroencephalogram or EEG, brain oxygen saturation, stimulus response, electromyography or EMG, respiration based on acoustic through sensors, body oxygen saturation or other blood 40 analytes, pulse, hydration, blood pressure, perfusion, or other parameters or combinations of parameters. In another embodiment, various aspects of sedation could be assessed quantitatively or qualitatively based on a visual representation of the patient's sedation in the aspects including hypnosis, responsiveness, muscle relaxation or other clinically relevant facets of depth of anesthesia.

In an embodiment, the functionality of the depth of consciousness monitor 140 could be optionally controlled by the drug delivery device 160. In an embodiment, the data 50 and qualitative and quantitative assessments of a patient's wellness being could be displayed on one or more of the depth of consciousness monitor 140, the drug delivery device 160, or any other device or system in communication with the depth of consciousness monitoring system 100 55 (e.g., a pulse oximeter, physiological patient monitor, nurse station, etc.). Also, audible alarms and other indicators could be displayed on either or both the depth of consciousness monitor 140 and drug delivery device in response to various threshold breaches based on the assessment of the patient's 60 wellness and depth of consciousness as determined from the various monitored parameters.

FIG. 3 illustrates one embodiments of a sensor 120 in the form of an EEG sensor 410, which is configured for placement on a patient's forehead to generate an EEG signal. 65 Disposable and reusable portions of the sensor 410 may be connected and overlayed on top of one another. The EEG

12

sensor 410 includes six EEG electrodes 440 with two reference electrodes (along the central axis of the EEG sensor 410) and four active channel electrodes (two on each side of the EEG sensor's central axis). In some embodiments, light source(s) and light detector(s) (not shown) may be incorporated into the EEG sensor 410, as well. All or some of the above mentioned sensor components including the EEG electrodes 440, leads from the electrodes 440, and blood oxygen detecting light emitters and detectors (when provided) may communicate with one or more chips 420 that enables transmission of acquired signals and drive signals. In some embodiments a single chip 420 is provided. In other embodiments, each component communicates with its own individual chip through wires, or printed circuits, or other suitable electrical connections.

The EEG electrodes 440 may be any suitable electrodes for detecting the electro-potentials on the surface of the skin of a patient's head. In one embodiment, EEG electrodes 440 include a metal or other suitable conductor and utilize leads contacting the surface of the skin. In another embodiment, the electrodes 440 are gelled electrodes that make contact through the skin via gel and have metal leads that come into contact with the gel. In still yet another embodiment, the EEG electrodes 440 may be glued to the forehead with any suitable patient dermal adhesive for connecting the EEG electrodes 440 and may have electrical conductivity. In an embodiment, potentials from the EEG electrodes 440 are transmitted to the depth of consciousness monitor 140 for further conditioning, transmitting or processing.

The sensor 410 may also include one or more temperature sensors (not shown). The temperature sensor may be any suitable sensor that can detect the temperature of the surface of the skin or other patient temperatures. In an embodiment, the temperature sensor may include a thermistor attached to a reusable portion of the sensor 410.

In an embodiment, the sensor 410 includes an interface 450 to couple the sensor 410 to the depth of consciousness monitor 140. The interface 450 may be any suitable electrical or data connection or communication port or device including, for example, a pin connector and receiver. Various other communication or electrical connections known in the art may be utilized. In an embodiment, the interface 450 may include an inductance connection utilizing transformers to couple a data and electrical connection across an insulator. In another embodiment, the interface 450 provides a data or electronic coupling between a reusable portion and a disposable portion of the sensor 410.

In some embodiments, the sensor 410 includes a disposable portion (not shown) removably attached to a reusable portion (not shown). In an embodiment, the disposable portion attaches to a measurement site of a patient's head and provides a base to which the reusable portion may be docked, mated or connected. The disposable portion houses the components of the sensor 410 that may be less expensive than at least some of the components contained in the reusable portion, and therefore may be disposed after a single or multiple uses, either on the same patient or different patients. The disposable portion of the sensor 410 includes a tape substrate that provides a base or substrate to which at least some of the components of the disposable portion may adhere or be integrated. In an embodiment, the tape can be constructed from any suitable disposable material that will effectively hold the components includes in the disposable portion to a patient's forehead or other measurement site. In an embodiment, the tape includes a suitable dermal adhesive on a patient side of the disposable portion for temporary adhesion of the sensor to a patient's skin.

In an embodiment, the sensor 410 may include an adhesive tape 430 that supports the EEG electrodes 440. In one embodiment, the EEG electrodes 440 may be fastened to the tape 430. In an embodiment, the EEG electrodes 440 could be embedded in the tape 430 by any known adhesive in the 5 sensor arts or any other suitable means for connecting the EEG electrodes 440 that would allow the EEG electrode 440 leads to be exposed on a patient side of tape 430 in an appropriate position to come in close proximity to a measurement site of a patient's skin. In an embodiment, EEG electrodes 440 may be gelled so that the gel contacts the electrodes and a measurement site of a patient's skin to provide an electrical path between the measurement site of the patient's skin and the EEG electrodes 440. In an embodiment, the leads of the EEG electrodes 440 are connected to 15 a chip 420 by wires or other suitable electrical connections, such a as a printed circuit, flex circuit, etc.

The sensor 410 may also include a temperature sensor (not shown). In an embodiment, the temperature sensor includes a thermistor with the thermistor leads exposed on a 20 patient contacting side of the tape 430, in order to facilitate the contacting of the leads of temperature sensor to a measurement site of a patient's skin. In an embodiment, the temperature sensor is connected to single chip through wires or other suitable electrical connections such as a flexible 25 printed circuit. In an embodiment, the temperature sensor may be located anywhere on the tape 430, the disposable portion or the reusable portion of the sensor 410 (if the sensor is provided with disposable and reusable portions). In an embodiment, the leads for the temperature sensor may be 30 near the center of tape 430 or anywhere on the periphery of tape 430.

In some embodiments, the sensor 410 includes a pulse oximeter sensor (not shown). The pulse oximeter sensor can include an ear pulse oximeter sensor that emits and detects 35 radiation to determine the oxygenation of the blood travelling through the arteries of the ear. Many suitable ear pulse oximeter sensors are known in the art such as those sensors commercially available from Masimo Corporation and disclosed herein with reference to U.S. Pat. No. 7,341,599, 40 which is expressly incorporated by reference in its entirety. In another embodiment, the pulse oximeter sensor may be a forehead pulse oximeter sensor or any other suitable pulse oximeter known in the art or disclosed herein. The pulse oximeter sensor may be connected to the sensor 410 through 45 electrical wires, wirelessly or other suitable electrical or data connection. Data collected from the pulse oximeter sensor may be transmitted to the depth of consciousness monitor 140, pulse oximeter, or both for conditioning and further processing.

In some embodiments, signal processing and conditioning circuitry of depth of consciousness monitor configured to monitor the EEG signals of a patient and providing feedback on the depth of sedation or awareness of a patient undergoing anesthesia, may be partially or entirely incorporated into the sensor 410. Sedation brain function monitors, including those similar to the SEDLINE sedation monitor commercially available from Masimo Corporation of Irvine, CA, as well as those described in U.S. Pat. Nos. 6,128,521, 6,301, 493, 6,317,627, 6,430,437, all of which are expressly incorporated by reference in their entireties. For example, the sensor's connector or interface 450 may house the circuit board, with six channels for six detectors and a processor configured to determine depth of consciousness.

Integration of all or the majority of the associated cir- 65 cuitry and processing components of several different patient monitoring sensors in a single sensor advantageously

14

provides a caregiver a simple device that can be attached to the patient's forehead and/or other areas on the patient, to provide minimal discomfort to the patient and minimal amount of wires and connections to cause electrical interference with instruments in the hospital environment. Additionally, the caregiver will spend less time attaching various sensors to a patient where each would otherwise require its own associated monitoring station. Furthermore, integration of sensor processing components allows some of the processing components to have shared functionality and therefore saves considerably on manufacturing costs. For example, memory chips, processors, or other electrical components may be shared by the various sensors. EEG Signal Processing

Referring again to FIG. 2, the depth of consciousness monitor's processor 220 is configured to receive at least an EEG signal from an EEG sensor 330 using an interface, such as an EEG interface 332 and process the EEG signal to determine the patient's depth of consciousness. In some embodiments, the processor 220 determines an index value between 0 and 100 to indicate depth of consciousness. The depth of consciousness monitor 140 may include a display, such as a monitor, LED, speaker, etc., to indicate the patient's depth of consciousness, e.g., the index value.

In some embodiments, the processor 220 determines the frequency content of the EEG signal prior to administration of any sedatives as well as during sedation. FIG. 4 illustrates one embodiment of a graph 500 showing the patient's EEG's frequency content or frequency spectrum prior to sedation as curve 510 and during sedation as curve 530. Shifting of the curve 510 amplitude at frequencies below 10 Hz, a drop in curve slope at frequencies above 10 Hz, and the formation or increase in the frequency curve 510 to form a local maximum (e.g., local maximum 540) at 10 Hz each indicates that the patient has entered a sedated state.

Indeed, in one embodiment, the processor 220 determines whether the patient is adequately sedated by monitoring for the presence of a local maximum 540 in the frequency curve 530 above a predetermined threshold value, at 10 Hz. However, the shape of the frequency curve 530 can vary based upon several factors, such as any one or more of the patient's age, age classification (e.g., pediatric, adult, geriatric, etc.), sex, weight, body-mass index, genetic factors, etc. The shape of the frequency curve 530 can also vary based upon one or more physiological parameters associated with the patient, such as the patient's temperature, blood oxygen concentration, EMG signal, etc. Furthermore, the shape of the frequency curve 530 can also vary based upon the particular drug administered to sedate the patient. For example, the drug type, drug class (e.g., hypnotic, analgesic, opiate, etc.), mechanism or method of delivery (inhalant, intravenous, ingestible, etc.) and/or particular active ingredient (e.g., Propofol (TIVA), Sevoflurane, nitrous oxide, morphine, etc.) can each affect the shape of the frequency curve 530. Variations in the frequency curve 530 make it more difficult for the depth of consciousness monitor 140 to accurately determine whether the patient is adequately sedated.

Therefore, to improve accuracy, in one embodiment the depth of consciousness monitor's processor 220 analyzes the frequency curve 530 by considering one or more curve profiles associated with the patient and/or the drug administered. For example, in one embodiment, the processor 220 obtains physiological information regarding the patient from sensors 120 attached to the depth of consciousness monitor 140. In other embodiments, the processor 220 obtains physiological information regarding the patient via a data port.

For example, the data port can receive temperature, blood oxygen saturation, respiration rate, and/or other physiological parameter information from an separate monitor. In addition, the depth of consciousness monitor 140 can receive additional information regarding the patient and the 5 drug via the data port, as well.

For example, in some embodiments, the data port includes a wireless radio, a network adapter, a cable, an Ethernet adapter, a modem, a cellular telephone, etc., to receive patient and/or drug information. The patient and/or drug 10 information is provided to the processor 220 to accurately interpret the frequency curve 530 derived from the EEG sensor 330 signal. In one embodiment, the data port includes a keyboard or other data entry device that allows the clinician to manually inter data relating a patient or drug 15 parameters, such as those examples described above. Indeed, the processor 220 can include one or more EEG processing engines that are configured based upon the patient and/or drug data received by the depth of consciousness monitor 140, as discussed in greater detail below.

In some embodiments, the patient's frequency response graph 500 is processed as four distinct, non-overlapping frequency bands 550, 552, 554, 556. For example, the first frequency band, sometimes referred to as the delta band, is the portion of the graph 500 between 0 and 4 or about 4 Hz. 25 The second frequency band, sometimes referred to as the theta band, is the portion of the graph 500 between 4 or about 4 Hz and 7 or about 7 Hz. The third frequency band, sometimes referred to as the alpha band, is the portion of the graph 500 between 7 or about 7 Hz and 12 or about 12 Hz; 30 and the fourth frequency band, sometimes referred to as the beta band, is the portion of the graph 500 greater than 12 or about 12 Hz.

In some embodiments, the depth of consciousness monitor 140 determines whether there is a peak 540 greater than 35 a predetermined threshold in the frequency curve 530 anywhere within the alpha band 554. If so, the monitor 140 may determine that the patient is adequately sedated. However, in some cases, the peak 540 can shift and appear outside of the alpha band 554. For example, a sedated patient that is 40 experiencing hypothermia may not manifest a peak in the alpha band; instead, the peak may shift to the theta or beta bands.

Therefore, in one embodiment, the depth of consciousness monitor **140** does not limit its search for a peak **540** to a 45 particular frequency value (e.g., 10 Hz) or a particular frequency band (e.g., alpha band **554**). Instead, in such an embodiment, the depth of consciousness monitor **140** scans across all frequencies (or a larger subset of frequencies than just those within the alpha band) to search for a peak **540** 50 (e.g., across two or more frequency bands). A detected peak may be used to determine alone (or in combination with other patient and/or drug data) whether the patient is adequately sedated.

The peak **540** can be defined in any of a variety of 55 clinically-relevant manners. For example, the peak **540** can be defined based upon the slope of the curve segment on one or both sides of the peak **540**, the relative magnitude of the peak compared to the curve values at predetermined locations or offsets on either side of the peak **540**, the relative 60 magnitude of the peak compared to the frequency curve **510** of the patient obtained prior to sedation, etc.

In one embodiment, the processor 220 processes the patient's frequency spectra curve 510, 530 as deformable curves by utilizing motion vector processing. For example, 65 the processor 220 compares each point (or a predetermined number of points) in the pre-sedation curve 510 to points

16 on frequency c

within the sedation frequency curve 530 to match points having the greatest similarity (e.g., relative position with respect to its neighbors, pattern matching, sum of absolute differences, any pattern matching technique, etc.). The processor 220 determines one or more motion vectors 560 to describe the motion of the points from one curve 510 to the next 530. Each motion vector 560 includes both direction and amplitude (e.g., distance traveled) information. Although the graph 500 includes curve 510, 530 illustrated in the frequency domain (the x-axis represents frequency), the motion vectors 560 include time domain information. For example, the processor 220 can look at multiple frames of data (e.g., multiple graphs 500) and employ pattern matching techniques (e.g., sum of absolute differences) to determine which points in the graphs 500 and their curves 510, 530 to use to define the respective motion vectors 560. In some embodiments, the motion vectors 560 are determined at 0.5, 1, 2, or 2.5 Hz intervals.

One or more motion vector 560 profiles may be con-20 structed based upon particular drug and patient data. For example, each drug used for sedation may be characterized by a unique set of motion vectors. When a patient is treated with a particular drug, and the patient's motion vectors match those of the drug (e.g., the drug profile), the processor 220 can determine that the patient is adequately sedated. Such profiles may be determined for any one or more of the patient's age, age classification (e.g., pediatric, adult, geriatric, etc.), sex, weight, body-mass index, genetic factors, etc., physiological parameters associated with the patient, such as the patient's temperature, blood oxygen concentration, EMG signal, etc., the particular drug administered to sedate the patient, the drug type, drug class (e.g., hypnotic, analgesic, opiate, etc.), mechanism or method of delivery (inhalant, intravenous, ingestible, etc.) and/or particular active ingredient (e.g., Propofol (TIVA), Sevoflurane, nitrous oxide, morphine, etc.). Such profiles may be stored within the depth of consciousness monitor's memory, or they may be retrieved from one or more data repositories stored at one or more remote locations (e.g., over a computer network, over the Internet, from a server, from the cloud, etc.).

In another embodiment, the EEG front end circuitry is configured not to eliminate or filter out low frequencies. The EEG front end circuitry instead allows the processor 220 to determine slow waves (e.g., time-domain signals at or below 1, 0.5, and/or 0.2 Hz). The processor 220 can employ one or more phase coherence methods to detect phase coherence between one or more slow waves and one or more patient signals falling within one of the frequency bands 550, 552, 554, 556. For example, in some embodiments, phase coherence between a slow wave and a signal from the theta band 552 indicates that the patient is awake. Once the slow wave and signal from the theta band 552 are out of phase, the patient is sedated. In other embodiments, phase coherence analysis is performed to compare phase coherence between a selected slow wave and a different frequency band's signals (e.g., the delta band 550, the alpha band 554, and/or the beta band 556). In some embodiments, the processor 220 performs phase coherence analysis between a selected slow wave and multiple signals between 4 and 50 Hz, e.g., every 0.2, 0.5, 1, or 2 Hz. In other embodiments, phase coherence is determined along the entire frequency spectrum.

In yet another embodiment, the processor 220 generates and/or utilizes a mathematical or electrical model of brain activity to determine whether the patient is adequately sedated. The model can be used to predict what the EEG of a sedated patient should look like based upon a particular

drug, drug delivery mechanism, concentration (or any other drug parameter, including those discussed above). Actual EEG signals may be compared to the signal predicted by the model to determine whether the patient is adequately sedated. The model can be constructed of various combinations of electrical components (e.g., resistors, capacitors, amplifiers, etc.) or computing elements.

In one embodiment, brain modeling occurs by storing EEG signals from sedated patients in a memory location and categorized the EEG signals based upon any of a variety of drug and patient data information. For example, sedated EEG signals may be categorized based upon the particular drug, dosage, concentration, delivery method, etc. used to treat the patient. A brain response model is constructed by combing the various data into a single model.

In some embodiments, the processor 220 includes a pre-processor 602, a compute engine 604, and a post processor 606, as illustrated in FIG. 5. The patient's EEG signal is received by the pre-processor 602. The pre-processor 602 performs front end processing, such as one or more of 20 filtering, amplification, A/D sampling, decimation, demodulation, etc. of the EEG signal. In some embodiments, the pre-processor 602 includes the EEG front end functionality discussed above with respect to FIG. 2. The compute engine **604** determines the level of patient sedation and/or depth of 25 consciousness utilizing, for example, any of the techniques described herein. In one embodiment, the compute engine 604 determines an index value representative of the patient's sedation level. The post-processor 606 provides an indication of the patient's sedation level as well as other relevant 30 information (e.g., system delay, as discussed above, other physiological parameter information, pass-through signals, etc.) for display to the clinician and/or transmission to a drug delivery device or other physiological monitor or information display station. In some embodiments, the post-proces- 35 sor 606 stores patient sedation, EEG signals, patient data and drug information in a memory location.

Another embodiment of a processor 220 is illustrated in FIG. 6. The processor 220 includes a pre-processor 602, multiple compute engines 604a, 604b, . . . 604n, and 40 decision logic 608. Each compute engine 604a, 604b, . . . 604n determines patient sedation information utilizing different processing approaches. For example, one compute engine 604 may determine patient sedation information utilizing motion vector analysis (e.g., as discussed above), 45 one compute engine 604 may determine patient sedation information utilizing frequency coherence analysis (e.g., as discussed above), etc. Furthermore, each compute engine 604 can be drug or patient information specific. For example, the compute engine 604 may utilize historical 50 information (either of the patient himself or from a model, etc.) to determine patient sedation. Each compute engine 604 could therefore correspond to a particular patient's age, age classification (e.g., pediatric, adult, geriatric, etc.), sex, weight, body-mass index, genetic factors, etc., physiological 55 parameters, such as temperature, blood oxygen concentration, EMG signal, etc., the particular drug administered to sedate the patient, such as the drug type, drug class (e.g., hypnotic, analgesic, opiate, etc.), mechanism or method of delivery (inhalant, intravenous, ingestible, etc.) and/or par- 60 ticular active ingredient (e.g., Propofol (TIVA), Sevoflurane, nitrous oxide, morphine, etc.). The compute engines 604 may operate simultaneously to parallel process EEG information.

A decision logic module **608** receives the outputs of each 65 compute engine **604** and applies logic to determine the best estimate of the patient's sedation level. For example, in

some embodiments, the decision logic module 608 averages or weighted averages the outputs of the compute engines 604. In other embodiments, the decision logic module 608

18

604. In other embodiments, the decision logic module 608 selects one or more compute engine outputs based upon known information about the patient and/or drug(s) used for sedation. The decision logic output 610 can indicate one or more parameters relevant to patient sedation. For example, in some embodiments, the decision logic output 610 includes suppression bar, EMG estimation, patient sedation index, drug type and patient age estimates. If any one or more decision logic outputs do not match actual drug or patient profile information, an alarm can activate. In other embodiments, the clinician manually compares the decision logic outputs to actual drug and patient profile information to confirm the accuracy of the depth of consciousness monitor 140.

Another embodiment of a depth of consciousness monitor's processor 220 is illustrated in FIG. 7. The processor 602 includes a pre-processor 602, compute engines 604 and decision logic 608, as discussed above with respect to FIG. 6. In addition, the processor 220 includes an EEG engine **620** and an EMG engine **630**. The EEG and EMG engines receive a pre-processed EEG signal from the pre-processor 602. The pre-processed EEG signal will generally contain both EEG and EMG content. For example, EEG content describes the electrical activity within the patient's brain and the EMG content describes the electrical activity associated with the muscular contractions in the patient's forehead, near the EEG sensor. The EEG and EMG engines 620, 630 separate the EEG and EMG content from the pre-processed EEG signal. The outputs of the EEG and EMG engines 620, 630 communicate with the inputs of one or more compute engines 604. The EEG signal from the EEG engine provides an indication of the patient's hypnotic state, while the EMG engine provides an indication of the patient's analgesic response, or pain state. Separating the two provides more information about the patient's state, and allows improved depth of consciousness processing. When EMG content is included in the EEG signal, the frequency response curve is flatter at higher frequencies (e.g., at frequencies in the beta band).

FIG. 8 illustrates one embodiment of a process 700 to determine a patient's sedation level that can be implemented by any of the processors described above. The process 700 begins at block 702. At block 702, the process 700 receives an EEG signal from a patient. At block 704, the process 700 receives treatment data. The treatment data may include one or more of patient data and drug profile information. The patient data can include any of the patient data or drug profile information described above. At block 706, the process 700 selects a computing engine based upon one or more treatment data. At block 708, the process 700 computes patient sedation information using EEG information and the selected computing engine. The patient sedation information can include one or more of a patient sedation level or index, an EMG level, a prediction of the drug used to sedate the patient, a prediction of the patient's age, etc. The process 700 ends at block 708.

FIG. 9 illustrates another embodiment of a process 800 to determine a patient's sedation level that can be implemented by any of the processors described above. The process 800 begins at block 802. At block 802, the process 800 receives an EEG signal from a patient. At block 804, the process 800 receives treatment data. The treatment data may include one or more of patient data and drug profile information. The patient data can include any of the patient data or drug profile information described above. At block 806, the

process **800** computes patient sedation information with parallel computing engines using the EEG information. The patient sedation information can include one or more of a patient sedation level or index, an EMG level, a prediction of the drug used to sedate the patient, a prediction of the patient's age, etc. At block **808**, the process **800** determines patient sedation information by selecting the output of one of the parallel computing engines, or by combining one or more computing engine outputs (e.g., averaging, weighted averaging, etc.). The process **800** ends at block **808**.

FIG. 10 illustrates one embodiment of a depth of consciousness monitoring system 1000. The system 1000 includes a depth of consciousness monitor assembly 1002, a multi-parameter monitor 1012, and a sensor 1014. The monitor assembly 1002 includes a depth of consciousness 15 processor 1003, which can include any of the processors described above. In some embodiments, the processor 1003 is configured to perform one or more of the methods described above.

The assembly 1002 may be provided in the form of a 20 cable. For example, the assembly 1002 may include one or more cables 1004 (or cable portions) that terminate in connectors 1005, 1008 located at the cable ends 1006, 1010. In the illustrated embodiment of FIG. 10, the assembly 1002 includes two cables 1004. The first cable 1004 has two ends 25 and is coupled to the processor 1003 at one end and terminates at a connector 1005 at the other end 1006. In one embodiment, the connector 1005 (which is one embodiment of an interface, such as a multi-parameter monitor interface) is configured facilitate communication between the proces- 30 sor 1003 and a medical device, such as a physiological monitor, display instrument, and/or a multi-parameter monitor 1012, etc. In some embodiments, the connector 1005 receives power from a multi-parameter monitor 1012 to power the depth of consciousness processor 1003. In some 35 embodiments, the processor 1003 is configured to consume less than about 250 mW, 500 mW or 1 W at about 4.75 V, 5 V or 5.25 V.

Physiological signals generated by the depth of consciousness processor 1003 are communicated to the multiparameter monitor 1012 via the connector 1005. The multiparameter monitor 1012 is configured to display one or more of the signals generated by the depth of consciousness processor 1003. In one embodiment, the cable 1004 that terminates at the multi-parameter monitor 1012 connector 45 1005 is configured to provide and/or receive power, ground, data+ and data- signals. For example, in one embodiment, the cable 1004 includes four conductors, one each for power, ground, data+ and data-.

An adapter or coupler (not shown) may be provided to 50 facilitate coupling of the connector 1005 to the multiparameter monitor 1012. For example, an adapter having first and second ends can be configured to have different shapes and pin configurations to allow communication and physical coupling of the connector 1005 to the multiparameter monitor 1012. In some embodiment, the adapter (not shown) also includes conditioning circuitry to facilitate communication and/or power transmission between the multiparameter monitor 1012 and the processor 1003. For example, the adapter may provide voltage regulation, electrical isolation, signal multiplexing, etc.

The second cable 1004 has two ends and is coupled to the processor 1003 at one end and terminates at a connector 1008 at the other end 1010. In one embodiment, the connector 1008 is configured to facilitate communication with 65 a physiological sensor 1014, such as an EEG sensor, and/or any other sensor described above via an interface 1015 (e.g.,

20

interface 450 of FIG. 3). In one embodiment, power from the multi-parameter monitor 1012 is directly or indirectly (e.g., after further filtering, conditioning, pulsing, etc. by the processor 1003) communicated to the sensor 1014. Signals (e.g., e.g., measured patient signals) from the sensor 1014 are communicated to the processor 1003 via the interface 1015, which can be coupled to the connector 1008.

FIG. 11 illustrates another embodiment of a depth of consciousness monitoring assembly 1002 coupled to a multi-parameter monitor (sometimes referred to as a multiparameter instrument) 1012. The multi-parameter monitor 1012 is configured to receive and display a plurality of physiological parameters received from a patient monitoring device, such as, but not limited to, the depth of consciousness monitoring assembly 1002. The multi-parameter monitor 1012 includes a display 1020. The display 1020 is configured to display a plurality of physiological signals 1022 related to a medical patient. In some embodiments, the display 1020 can be configured to display only selected or groups of physiological signals 1022. In some embodiments, the monitor 1012 can be configured to display a particular view or mode on the display 1020. The view or mode can include one or more pre-selected groupings of physiological signals to display. Examples of different views that may be provided via the display 1020 are discussed below with respect to FIGS. 14-16. Other views, in addition to or instead of those illustrated in FIGS. 14-16 may be displayed on the multi-parameter monitor 1012 display 1020, as well.

In some embodiments, the multi-parameter monitor 1012 also includes a removable module 1024. The removable module 1024 can include a physiological monitor configured to determine one or more physiological parameters associated with the medical patient. For example, in some embodiments, the removable module 1024 includes a respiration rate monitor, a blood oxygen saturation monitor, a blood gas monitor, a carbon monoxide monitor, an ECG monitor, an EKG monitor, a blood pressure monitor, a temperature monitor, a heart rate monitor, etc., or a combination of any one or more of the foregoing.

In the illustrated embodiment of FIG. 11, the depth of consciousness monitor assembly 1002 only includes one cable 1004. A first end of the cable 1004 terminates at a connector (not shown) that is attached to the multi-parameter monitor 1012. The second end of the cable 1003 includes the depth of consciousness processor 1003 and connector 1008, which are integrated within a single housing assembly. The connector end of a sensor 1014 is shown attached to the depth of consciousness monitor assembly's 1002 cable's 1003 second end.

FIG. 12 illustrates another embodiment of a depth of consciousness monitor assembly 1002. The processor 1003 is positioned between the ends 1006, 1010 of the assembly 1002. The length of the cable 1004 attached to the connector 1008 configured to attach to a sensor (not shown) may be shorter than the length of the cable 1004 attached to the connector 1005 configured to attach to the multi-parameter monitor (not shown). The shorter sensor cable 1004 length can provide additional comfort and less pulling on the sensor when attached to the patient. FIG. 13 illustrates the depth of consciousness monitor assembly 1002 coupled to a sensor 1014. The sensor 1014 can include any of the EEG sensors described above.

FIGS. 14-16 illustrate views of various parameters 1022 that may be displayed on the multi-parameter monitor 1012 display 1020. The embodiment of FIG. 14 illustrates an EEG view of a multi-parameter monitor 1012. The multi-parameter monitor 1012 view includes a numeric value indicator

(e.g., EEG data, insufficient EEG data, patent state index (PSI) value), or any other value described herein, etc.), a bar-graph indicator, menu indicators, date and time indicators, message indicators, physiological waveform indicators, and system status indicators. The physiological waveform 5 indicators can display each of the waveforms received from each electrode (e.g., R2, R1, L1) of an sensor 1014, such as an EEG sensor.

FIG. 15 illustrates a trend view of a multi-parameter monitor 1012. The multi-parameter monitor 1012 view includes a primary indicator or display and a secondary indicator or display. The primary indicator displays the trend of one or more physiological parameters (e.g., PSI, etc.) over time. One or more secondary indicators can display additional physiological parameters of the medical patient, 15 including but not limited to, EMG, and SR. In one embodiment, the secondary indicators display information in the same format (e.g., waveform, solid waveform, bargraph, etc.) as the primary (e.g., trend plot) indicator, but at a smaller size. In other embodiments, the secondary indicators 20 display information in a different format than the primary (e.g., trend plot, etc.) indicator. FIG. 16 illustrates a density spectral array view of a multi-parameter monitor 1012. The multi-parameter monitor 1012 view includes a spectral density indicator

Each of the displayed physiological parameters can be determined by the depth of consciousness processor 1003. In addition, the multi-parameter monitor 1012 can be configured to display any one or more of the parameters discussed above, as well as other parameters, such as signals from the 30 removable module 1024, when provided.

All publications, patents, and patent applications mentioned in this specification are herein incorporated by reference to the same extent as if each individual publication, patent, or patent application was specifically and individu- 35 ally indicated to be incorporated by reference.

Depending on the embodiment, certain acts, events, or functions of any of the processes or algorithms described herein can be performed in a different sequence, can be added, merged, or left out altogether (e.g., not all described 40 described, and pointed out novel features as applied to operations or events are necessary for the practice of the algorithm). Moreover, in certain embodiments, operations or events can be performed concurrently, e.g., through multithreaded processing, interrupt processing, or multiple processors or processor cores or on other parallel architectures, 45 rather than sequentially.

The various illustrative logical blocks, modules, routines, and algorithm steps described in connection with the embodiments disclosed herein can be implemented as electronic hardware, computer software, or combinations of 50 both. To clearly illustrate this interchangeability of hardware and software, various illustrative components, blocks, modules, and steps have been described above generally in terms of their functionality. Whether such functionality is implemented as hardware or software depends upon the particular 55 application and design constraints imposed on the overall system. The described functionality can be implemented in varying ways for each particular application, but such implementation decisions should not be interpreted as causing a departure from the scope of the disclosure.

The steps of a method, process, routine, or algorithm described in connection with the embodiments disclosed herein can be embodied directly in hardware, in a software module executed by a processor, or in a combination of the two. A software module can reside in RAM memory, flash 65 memory, ROM memory, EPROM memory, EEPROM memory, registers, hard disk, a removable disk, a CD-ROM,

or any other form of a non-transitory computer-readable storage medium. An example storage medium can be coupled to the processor such that the processor can read information from, and write information to, the storage medium. In the alternative, the storage medium can be integral to the processor. The processor and the storage medium can reside in an ASIC. The ASIC can reside in a user terminal. In the alternative, the processor and the storage medium can reside as discrete components in a user terminal.

22

Conditional language used herein, such as, among others, "can," "could," "might," "may," "e.g.," and the like, unless specifically stated otherwise, or otherwise understood within the context as used, is generally intended to convey that certain embodiments include, while other embodiments do not include, certain features, elements and/or steps. Thus, such conditional language is not generally intended to imply that features, elements and/or steps are in any way required for one or more embodiments or that one or more embodiments necessarily include logic for deciding, with or without author input or prompting, whether these features, elements and/or steps are included or are to be performed in any particular embodiment. The terms "comprising," "including," "having," and the like are synonymous and are used inclusively, in an open-ended fashion, and do not exclude additional elements, features, acts, operations, and so forth. Also, the term "or" is used in its inclusive sense (and not in its exclusive sense) so that when used, for example, to connect a list of elements, the term "or" means one, some, or all of the elements in the list.

Conjunctive language such as the phrase "at least one of X, Y and Z," unless specifically stated otherwise, is to be understood with the context as used in general to convey that an item, term, etc. may be either X, Y, or Z, or a combination thereof. Thus, such conjunctive language is not generally intended to imply that certain embodiments require at least one of X, at least one of Y and at least one of Z to each be

While the above detailed description has shown, various embodiments, it can be understood that various omissions, substitutions, and changes in the form and details of the devices or algorithms illustrated can be made without departing from the spirit of the disclosure. As can be recognized, certain embodiments of the inventions described herein can be embodied within a form that does not provide all of the features and benefits set forth herein, as some features can be used or practiced separately from others. The scope of certain inventions disclosed herein is indicated by the appended claims rather than by the foregoing description. All changes which come within the meaning and range of equivalency of the claims are to be embraced within their scope.

What is claimed is:

- 1. A depth of consciousness monitor configured to determine a level of sedation of a medical patient, the depth of consciousness monitor comprising:
 - an EEG interface configured to receive an EEG signal from an EEG sensor;
 - an EEG front end configured to pre-process the EEG signal, wherein the EEG signal is assigned a first time
 - a processor, configured to determine the level of sedation of the medical patient based at least upon the preprocessed EEG signal, the processor comprising:

two or more parallel computing engines, each configured to receive as an input a same first time stamped

pre-processed EEG signal and compute a possible sedation level according to a different processing approach, each processing approach configured to simultaneously calculate the possible sedation level using the same first time stamped pre-processed EEG 5 signal; and

- a decision logic module, configured to arbitrate the possible sedation level computations as computed by the two or more parallel computing engines on the same first time stamped pre-processed EEG signal and based on the arbitration, determine a patient sedation index corresponding to an estimated level of sedation of the medical patient, wherein the arbitration comprises selecting a subset of possible sedation levels generated by the two or more parallel compute engines, wherein the arbitration is based at least on data associated with at least one sedation drug acting on the medical patient and the selected subset of possible sedation levels generated by the two or more parallel compute engines; and
- a data port configured to transmit the level of sedation of the medical patient.
- 2. The depth of consciousness monitor of claim 1, wherein the data port comprises a multi-parameter physiological

24

monitor interface configured to receive power from a multiparameter physiological monitor and provide at least the level of sedation of the medical patient to the multi-parameter physiological monitor.

- 3. The depth of consciousness monitor of claim 1, wherein at least one of the computing engines is configured to implement a motion vector process to compute one of the possible sedation levels.
- **4**. The depth of consciousness monitor of claim **1**, wherein at least one of the computing engines is configured to implement a phase coherence process to compute one of the possible sedation levels.
- 5. The depth of consciousness monitor of claim 1, wherein at least one of the computing engines is configured to utilize a brain model to compute one of the possible sedation levels.
- **6**. The depth of consciousness monitor of claim **1**, wherein the EEG front end comprises an EEG engine and an EMG engine configured to extract EEG information and EMG information from the EEG signal, respectively.
- 7. The depth of consciousness monitor of claim 1, wherein the data port comprises a display.
- **8**. The depth of consciousness monitor of claim **1**, wherein the data port comprises a wireless communication device.
