SYSTEMS AND METHODS FOR MITIGATING LANE-CHANGE DISTURBANCE BASED ON COOPERATIVE MANEUVERING

Abstract

A method for controlling longitudinal movements of vehicles is provided. The method includes obtaining traffic data from a target lane, determining whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data, identifying a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane, generating a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car-following models, and requesting that the identified connected vehicle drive based on the suggested speed profile.

Background/Summary

CROSS-REFERENCE TO RELATED APPLICATIONS [0001] The application is a divisional of U.S. patent application Ser. No. 17/830,776 filed on Jun. 2, 2022, the entire contents of which are herein incorporated by reference.

TECHNICAL FIELD
[0002] The present disclosure relates to systems and methods for mitigating lane-change disturbance based on cooperative maneuvering.
BACKGROUND
[0003] Drivers perform mandatory and/or discretionary lane-changes to follow their route or improve their trip experience. Mandatory lane change decisions are made based on routes, turning points, downstream blockages, while discretionary lane-change decisions are made based on general incentives such as increasing speed. Lane-change actions of vehicles can affect the efficiency of a traffic system. It has been shown that disturbances by lane-change actions in certain traffic densities can lead to traffic instabilities.
[0004] Traffic instabilities can result in stop-and-go waves which can reduce the capacity of the road and produce traffic congestion. Planning connected vehicles' (CVs) actions considering the potential impact on traffic stability can improve the performance of the CVs and the whole traffic.
[0005] Accordingly, a need exists for systems and methods that mitigate congestions caused by the lane-change maneuvers in mixed traffic (including various types of vehicles such as non-connected human-driven, connected non-cooperating vehicles, and connected cooperating vehicles) conditions.
SUMMARY
[0006] The present disclosure provides systems and methods for managing cooperative maneuvering among connected vehicles.
[0007] In one embodiment, a method for controlling longitudinal movements of vehicles is provided. The method includes obtaining traffic data from a target lane, determining whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data, identifying a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane, generating a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car-following models, and requesting that the identified connected vehicle drive based on the suggested speed profile.
[0008] In another embodiment, a system for mitigating traffic congestion is provided. The system includes a processor programmed to perform operations including obtaining traffic data from a target lane, determining whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data, identifying a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane, generating a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car-following models, and requesting that the identified connected vehicle drive based on the suggested speed profile.

[0009] These and additional features provided by the embodiments of the present disclosure will be more fully understood in view of the following detailed description, in conjunction with the drawings.

Description

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] The embodiments set forth in the drawings are illustrative and exemplary in nature and not intended to limit the disclosure. The following detailed description of the illustrative embodiments can be understood when read in conjunction with the following drawings, where like structure is indicated with like reference numerals and in which:

[0011] FIGS. **1**A and **1**B schematically depict an example scenario where unstable behavior of vehicles or string instability in a target lane is predicted in response to an ego vehicle changing lanes, in accordance with one or more embodiments shown and described herewith;

[0012] FIG. **2** depicts a schematic diagram of a traffic instabilities mitigation system, according to one or more embodiments shown and described herein;

[0013] FIG. **3** depicts a flowchart for performing a density reduction strategy in a target lane, according to one or more embodiments shown and described herein;

[0014] FIGS. **4**A, **4**B, and **4**C depict a density reduction strategy example where an ego vehicle cooperates with a connected vehicle, according to one or more embodiments shown and described herein;

[0015] FIG. **5** depicts an overall flowchart of performing density reduction, according to one or more embodiments shown and described herein;

[0016] FIG. **6** depicts a flowchart for performing longitudinal control in a target lane including both human-driven and connected cooperating vehicles, according to one or more embodiments shown and described herein;

[0017] FIGS. **7**A, **7**B, **7**C, and **7**D depict a longitudinal control strategy example where an ego vehicle cooperates with a connected vehicle, according to one or more embodiments shown and described herein;

[0018] FIG. **8** depicts an overall flowchart of performing longitudinal control including both human-driven and connected cooperating vehicles, according to one or more embodiments shown and described herein;

[0019] FIGS. **9**A, **9**B, **9**C, and **9**D depict an example of performing longitudinal control in a fully connected scenario, according to one or more embodiments shown and described herein;

[0020] FIGS. **10**A, **10**B, **10**C, **10**D, and **10**E depict an example of performing longitudinal control in a partially connected scenario, according to one or more embodiments shown and described herein; and

[0021] FIGS. **11**A and **11**B depict an overall flowchart of performing longitudinal control in a fully or partially connected scenario, according to one or more embodiments shown and described herein.

DETAILED DESCRIPTION

[0022] The embodiments disclosed herein include systems and methods for managing cooperative maneuvering among connected vehicles.

[0023] In embodiments, the present system mitigates lane-change disturbance based on cooperative maneuvering is provided. The system may predict that a traffic in the target lane **104** becomes string unstable in response to an ego vehicle **100** moving to the target lane **104** based on learned car-following models and the traffic data as illustrated in FIG. **1**B. As a density reduction strategy, the system identifies a connected vehicle **110** in the target lane **104** and requests that the identified connected vehicle **110** change lanes from the target lane **104** to another lane **106** as illustrated in

FIGS. **4**A-**4**C. As a longitudinal control strategy, the system may also identify a connected vehicle **110** and request that the identified connected vehicle **110** to slow down in the target lane **104** such that the identified connected vehicle **110** and the vehicles behind the identified connected vehicle **110** experience relatively stable driving as illustrated in FIGS. **7**A-**7**D.

[0024] FIGS. **1**A and **1**B schematically depict an example scenario where unstable behavior of vehicles or string instability in a target lane is predicted in response to an ego vehicle changing lanes, in accordance with one or more embodiments shown and described herewith.

[0025] In FIG. **1**A, an ego vehicle **100** identifies an obstacle in a lane **102**, and plans to change lanes from the lane **102** to a target lane **104**. In the target lane **104**, a connected vehicle **110** and unconnected vehicles **121**, **122**, **123**, **124**, **125**, and **126** are driving. Each of the ego vehicle **100**, the connected vehicle **110**, and the unconnected vehicles **121**, **122**, **123**, **124**, **125**, and **126** may be a vehicle including an automobile or any other passenger or non-passenger vehicle such as, for example, a terrestrial, aquatic, and/or airborne vehicle. Unconnected vehicles **127**, **128**, **129** are driving in a third land **106**. In some embodiments, each of the ego vehicle **100** and the connected vehicle **110** may be an autonomous driving vehicle.

[0026] The ego vehicle **100** may detect the presence of the connected vehicle **110** and the unconnected vehicles **121**, **122**, **123**, **124**, **125**, and **126** using sensors such as radar sensor, LIDAR sensors, cameras, or by communicating with the connected vehicle **110** via a vehicle-to-vehicle connection ("V2V connection"). The ego vehicle **100** may collect traffic information in the target lane **104**. The traffic information may include the presence and speed of connected or unconnected vehicles in the target lane **104**, the traffic density of vehicles in the target lane **104**, and the like. The presence, speeds, and/or accelerations of connected or unconnected vehicles in the target lane **104** may be obtained by the sensors of the ego vehicle **100**. The traffic density may be estimated by a world model. The world model receives sensor data, wireless messages, and GPS data as input, and outputs traffic density estimation for the target lane **104**.

[0027] FIG. **1**B depicts an example of the lane changing maneuver by the ego vehicle **100**. The system of the ego vehicle **100** may simulate the vehicles in the target lane **104** based on learned car-following models and collected traffic information. The car-following models may include, but not limited to, an optimal velocity model (OVM), intelligent driver model (IDM), and a Gipps car following model. As another example, a trained artificial intelligence model may consider the traffic density, dynamics of surrounding vehicles into account. In addition, this model may consider the trajectories that the ego vehicle, cooperative vehicles and other vehicles will take. Having an AI trained model or a lookup table trained on previous data in advance would allow for quick determination of which vehicle can cooperate with which vehicle, which may be critical in a dynamic task.

[0028] In this example, the ego vehicle **100** may turn on left turn signals and initiate lane changing maneuver. In response to the left turn signals and/or the lane changing maneuver, the unconnected vehicle **122** may slightly break to provide a space for the ego vehicle **100** in the target lane **104**. Then, the vehicles behind the unconnected vehicle **122** may further brake in response to the brake of the unconnected vehicle **122** as illustrated in FIG. **1**B. Specifically, the unconnected vehicle **123** may break further than the unconnected vehicle **122**, the unconnected vehicle **124** may break further than the unconnected vehicle **123**, the connected vehicle **110** may break further than the unconnected vehicle **124**, the unconnected vehicle **125** may break further than the connected vehicle **110**, and the unconnected vehicle **126** may break further than the unconnected vehicle **125**. This cascading of braking may lead to a stop-and-go jam and is referred to as string instability (a type of traffic instability).

[0029] The present system mitigates traffic instabilities by two approaches. One is a density reduction strategy and the other is a longitudinal control strategy, i.e., controlling acceleration of connected vehicles in the target lane. The density reduction strategy will be described with reference to FIGS. **3**-**5**, and the longitudinal control strategy will be described with reference to

FIGS. **6-11**.

[0030] FIG. **2** depicts a schematic diagram of a traffic instabilities mitigation system, according to one or more embodiments shown and described herein. The system includes an ego vehicle system **200**, and a connected vehicle system **220**.

[0031] It is noted that, while the ego vehicle system **200**, and the connected vehicle system **220** are depicted in isolation, each of the ego vehicle system **200**, and the connected vehicle system **220** may be included within a vehicle in some embodiments, for example, respectively within each of the ego vehicle **100**, and the connected vehicle **110** of FIG. **1**. While FIG. **2** depicts that the ego vehicle system **200** communicates with one connected vehicle system **220**, the ego vehicle system **200** may communicate with more than one connected vehicle system. In embodiments, each of the ego vehicle system **200** and the connected vehicle system **220** may be included within a vehicle that may be an automobile or any other passenger or non-passenger vehicle such as, for example, a terrestrial, aquatic, and/or airborne vehicle. In some embodiments, the vehicle may be an autonomous vehicle that navigates its environment with limited human input or without human input.

[0032] The ego vehicle system **200** includes one or more processors **202**. Each of the one or more processors **202** may be any device capable of executing machine readable and executable instructions. Accordingly, each of the one or more processors **202** may be a controller, an integrated circuit, a microchip, a computer, or any other computing device. The one or more processors **202** are coupled to a communication path **204** that provides signal interconnectivity between various modules of the system. Accordingly, the communication path **204** may communicatively couple any number of processors **202** with one another, and allow the modules coupled to the communication path **204** to operate in a distributed computing environment. Specifically, each of the modules may operate as a node that may send and/or receive data. As used herein, the term "communicatively coupled" means that coupled components are capable of exchanging data signals with one another such as, for example, electrical signals via conductive medium, electromagnetic signals via air, optical signals via optical waveguides, and the like.

[0033] Accordingly, the communication path **204** may be formed from any medium that is capable of transmitting a signal such as, for example, conductive wires, conductive traces, optical waveguides, or the like. In some embodiments, the communication path **204** may facilitate the transmission of wireless signals, such as WiFi, Bluetooth®, Near Field Communication (NFC), and the like. Moreover, the communication path **204** may be formed from a combination of mediums capable of transmitting signals. In one embodiment, the communication path **204** comprises a combination of conductive traces, conductive wires, connectors, and buses that cooperate to permit the transmission of electrical data signals to components such as processors, memories, sensors, input devices, output devices, and communication devices. Accordingly, the communication path **204** may comprise a vehicle bus, such as for example a LIN bus, a CAN bus, a VAN bus, and the like. Additionally, it is noted that the term "signal" means a waveform (e.g., electrical, optical, magnetic, mechanical or electromagnetic), such as DC, AC, sinusoidal-wave, triangular-wave, square-wave, vibration, and the like, capable of traveling through a medium.

[0034] The ego vehicle system **200** includes one or more memory modules **206** coupled to the communication path **204**. The one or more memory modules **206** may comprise RAM, ROM, flash memories, hard drives, or any device capable of storing machine readable and executable instructions such that the machine readable and executable instructions can be accessed by the one or more processors **202**. The machine readable and executable instructions may comprise logic or algorithm(s) written in any programming language of any generation (e.g., 1GL, 2GL, 3GL, 4GL, or 5GL) such as, for example, machine language that may be directly executed by the processor, or assembly language, object-oriented programming (OOP), scripting languages, microcode, etc., that may be compiled or assembled into machine readable and executable instructions and stored on the one or more memory modules **206**. Alternatively, the machine readable and executable instructions

may be written in a hardware description language (HDL), such as logic implemented via either a field-programmable gate array (FPGA) configuration or an application-specific integrated circuit (ASIC), or their equivalents. Accordingly, the methods described herein may be implemented in any conventional computer programming language, as pre-programmed hardware elements, or as a combination of hardware and software components. The one or more processors **202** along with the one or more memory modules **206** may operate as a controller for the ego vehicle system **200**.

[0035] The one or more memory modules **206** includes a density reduction module **207** and a longitudinal control module **209**. The density reduction module **207** and the longitudinal control module **209** work together or independently to mitigate expected traffic instabilities in a target lane, e.g., the target lane **104** in FIGS. **1**A and **1**B. Each of the density reduction module **207** and the longitudinal control module **209** may be a program module in the form of operating systems, application program modules, and other program modules stored in one or more memory modules **206**. In some embodiments, the program module may be stored in a remote storage device that may communicate with the ego vehicle system **200**, for example, in a cloud server or an edge server. Such a program module may include, but is not limited to, routines, subroutines, programs, objects, components, data structures, and the like for performing specific tasks or executing specific data types as will be described below.

[0036] In embodiments, the density reduction module **207** identifies a potential cooperating vehicle in a target lane based on traffic information in the target lane, and transmits a cooperation request to the identified cooperating vehicle. Once the density reduction module **207** receives an approval from the identified cooperating vehicle, the density reduction module **207** transmits an instruction to reduce density in the target lane, i.e., changing lanes from a current lane to another lane, to the identified cooperative vehicle. Then, the ego vehicle may change lanes from a current lane to the target lane. For example, by referring to FIG. **1**A, the ego vehicle **100** may transmits an instruction to the connected vehicle **110** to change lanes from the target lane **104** to the third lane **106**.

[0037] In embodiments, the longitudinal control module **209** identifies a potential cooperating vehicle in a target lane based on traffic information in the target lane, and determines whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on the traffic information and learned car following models. Then, the longitudinal control module **209** generates a speed profile for the identified cooperating vehicle based on the estimated potential oscillations. The longitudinal control module **209** transmits a cooperation request including the speed profile to the identified cooperating vehicle. Once the longitudinal control module **209** receives an approval from the identified cooperating vehicle, the longitudinal control module **209** transmits an instruction to follow the speed profile to the identified connected vehicle. Then, the ego vehicle may change lanes from a current lane to the target lane. For example, by referring to FIG. **1**A, the ego vehicle **100** may transmit an instruction to the connected vehicle **110** to slow down based on the speed profile received from the ego vehicle **100**.

[0038] Referring still to FIG. **2**, the ego vehicle system **200** comprises one or more sensors **208**. The one or more sensors **208** may be any device having an array of sensing devices capable of detecting radiation in an ultraviolet wavelength band, a visible light wavelength band, or an infrared wavelength band. The one or more sensors **208** may detect the presence of other vehicles such as the connected vehicle **110** and the unconnected vehicles **121**, **122**, **123**, **124**, **125**, and **126** in FIG. **1**, and/or the distance between the ego vehicle **100** and the connected vehicle **110** and the unconnected vehicles **121**, **122**, **123**, **124**, **125**, and **126**. The one or more sensors **208** may have any resolution. In some embodiments, one or more optical components, such as a mirror, fish-eye lens, or any other type of lens may be optically coupled to the one or more sensors **208**. In embodiments described herein, the one or more sensors **208** may provide image data to the one or more processors **202** or another component communicatively coupled to the communication path **204**. In some embodiments, the one or more sensors **208** may also provide navigation support. That is, data captured by the one or more sensors **208** may be used to autonomously or semi-autonomously

navigate the ego vehicle **100**.

[0039] In some embodiments, the one or more sensors **208** include one or more imaging sensors configured to operate in the visual and/or infrared spectrum to sense visual and/or infrared light. Additionally, while the particular embodiments described herein are described with respect to hardware for sensing light in the visual and/or infrared spectrum, it is to be understood that other types of sensors are contemplated. For example, the systems described herein could include one or more LIDAR sensors, radar sensors, sonar sensors, or other types of sensors for gathering data that could be integrated into or supplement the data collection described herein. Ranging sensors like radar sensors may be used to obtain a rough depth and speed information for the view of the ego vehicle system **200**.

[0040] The ego vehicle system **200** comprises a satellite antenna **214** coupled to the communication path **204** such that the communication path **204** communicatively couples the satellite antenna **214** to other modules of the ego vehicle system **200**. The satellite antenna **214** is configured to receive signals from global positioning system satellites. Specifically, in one embodiment, the satellite antenna **214** includes one or more conductive elements that interact with electromagnetic signals transmitted by global positioning system satellites. The received signal is transformed into a data signal indicative of the location (e.g., latitude and longitude) of the satellite antenna **214** or an object positioned near the satellite antenna **214**, by the one or more processors **202**.

[0041] The ego vehicle system **200** comprises one or more vehicle sensors **212**. Each of the one or more vehicle sensors **212** is coupled to the communication path **204** and communicatively coupled to the one or more processors **202**. The one or more vehicle sensors **212** may include one or more motion sensors for detecting and measuring motion and changes in motion of the ego vehicle **100**. The motion sensors may include inertial measurement units. Each of the one or more motion sensors may include one or more accelerometers and one or more gyroscopes. Each of the one or more motion sensors transforms sensed physical movement of the vehicle into a signal indicative of an orientation, a rotation, a velocity, or an acceleration of the vehicle.

[0042] Still referring to FIG. **2**, the ego vehicle system **200** comprises network interface hardware **216** for communicatively coupling the ego vehicle system **200** to the connected vehicle system **220**. The network interface hardware **216** can be communicatively coupled to the communication path **204** and can be any device capable of transmitting and/or receiving data via a network. Accordingly, the network interface hardware **216** can include a communication transceiver for sending and/or receiving any wired or wireless communication. For example, the network interface hardware **216** may include an antenna, a modem, LAN port, WiFi card, WiMAX card, mobile communications hardware, near-field communication hardware, satellite communication hardware and/or any wired or wireless hardware for communicating with other networks and/or devices. In one embodiment, the network interface hardware **216** includes hardware configured to operate in accordance with the Bluetooth® wireless communication protocol. The network interface hardware **216** of the ego vehicle system **200** may transmit its data to the connected vehicle system **220**. For example, the network interface hardware **216** of the ego vehicle system **200** may transmit vehicle data, location data, maneuver data and the like to other connected vehicles, a cloud server, edge servers, and the like.

[0043] The ego vehicle system **200** may connect with one or more external vehicle systems (e.g., the connected vehicle system **220**) and/or external processing devices (e.g., a cloud server, or an edge server) via a direct connection. The direct connection may be a vehicle-to-vehicle connection ("V2V connection"), a vehicle-to-everything connection ("V2X connection"), or a mmWave connection. The V2V or V2X connection or mmWave connection may be established using any suitable wireless communication protocols discussed above. A connection between vehicles may utilize sessions that are time-based and/or location-based. In embodiments, a connection between vehicles or between a vehicle and an infrastructure element may utilize one or more networks to connect, which may be in lieu of, or in addition to, a direct connection (such as V2V, V2X,

mmWave) between the vehicles or between a vehicle and an infrastructure. The ego vehicle system **200** may communicate with external communicate vehicle systems using wireless messages such as basic safety messages (BSMs), maneuver massages (MMs), and the like. BSM is a wireless message transmitted between vehicles where the transmitter sends its position, speed and other static/dynamic information. MM is a general class of wireless messages exchanged between road users and infrastructure that contains the future trajectory (or possible future trajectories) of the transmitting road user. Specific examples of such messages could be the Maneuver Coordination Message (MCM) or the Maneuver Sharing Coordination Message (MSCM).

[0044] By way of non-limiting example, vehicles may function as infrastructure nodes to form a mesh network and connect dynamically on an ad-hoc basis. In this way, vehicles may enter and/or leave the network at will, such that the mesh network may self-organize and self-modify over time. Other non-limiting network examples include vehicles forming peer-to-peer networks with other vehicles or utilizing centralized networks that rely upon certain vehicles and/or infrastructure elements. Still other examples include networks using centralized servers and other central computing devices to store and/or relay information between vehicles.

[0045] Still referring to FIG. **2**, the ego vehicle system **200** may be communicatively coupled to the connected vehicles system **220** or a cloud server by the network **250**. In one embodiment, the network **250** may include one or more computer networks (e.g., a personal area network, a local area network, or a wide area network), cellular networks, satellite networks and/or a global positioning system and combinations thereof. Accordingly, the ego vehicle system **200** can be communicatively coupled to the network **250** via a wide area network, via a local area network, via a personal area network, via a cellular network, via a satellite network, etc. Suitable local area networks may include wired Ethernet and/or wireless technologies such as, for example, Wi-Fi. Suitable personal area networks may include wireless technologies such as, for example, IrDA, Bluetooth®, Wireless USB, Z-Wave, ZigBee, and/or other near field communication protocols. Suitable cellular networks include, but are not limited to, technologies such as LTE, WiMAX, UMTS, CDMA, and GSM.

[0046] Still referring to FIG. **2**, the connected vehicle system **220** includes one or more processors **222**, one or more memory modules **226**, one or more sensors **228**, one or more vehicle sensors **233**, a satellite antenna **235**, and a communication path **224** communicatively connected to the other components of the connected vehicle system **220**. The components of the connected vehicle system **220** may be structurally similar to and have similar functions as the corresponding components of the ego vehicle system **200** (e.g., the one or more processors **222** corresponds to the one or more processors **202**, the one or more memory modules **226** corresponds to the one or more memory modules **206**, the one or more sensors **228** corresponds to the one or more sensors **208**, the one or more vehicle sensors **233** corresponds to the one or more vehicle sensors **212**, the satellite antenna **235** corresponds to the satellite antenna **214**, the communication path **224** corresponds to the communication path **204**, and the network interface hardware **236** corresponds to the network interface hardware **216**). The one or more memory modules **226** may store a density reduction module and a longitudinal control module similar to the density reduction module **207** and the longitudinal control module **209** of the ego vehicle system **200**.

[0047] FIG. **3** depicts a flowchart for performing a density reduction strategy in a target lane, according to one or more embodiments shown and described herein. The flowchart is described with reference to FIGS. **2** and **4**A-**4**C of the present application.

[0048] In step **310**, a controller of the ego vehicle obtains traffic data from a target lane. For example, by referring to FIG. **4**A, the ego vehicle **100** may obtain traffic data from the target lane **104**. The traffic data may include the presence and speed of connected or unconnected vehicles in the target lane **104**, the traffic density of vehicles in the target lane **104**, and the like. The presence and speed of connected or unconnected vehicles in the target lane **104** may be obtained by the sensors of the ego vehicle **100**. The traffic density may be estimated by a world model. The world

model receives sensor data, wireless messages, and GPS data as input, and outputs traffic density estimation for the target lane **104**. The ego vehicle **100** may also learn a car-following model of vehicles in the target lane **104**.

[0049] In step **320**, the controller of the ego vehicle determines whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data. For example, the controller of the ego vehicle **100** may simulate the ego vehicle changing lanes from the lane **102** to the target lane **104** in FIG. **1**B using the traffic data and the learned car following model obtained in step **310**. In some embodiments, the ego vehicle **100** may determine key performance indicators, e.g., traffic flow, driver comfort, and timeliness of the maneuver, caused by the lane changing maneuver of the ego vehicle **100** by running simulations of the ego vehicle **100** and vehicles in the target lane **104**. The simulation may use IDM (intelligent driving model) for upstream vehicles. Based on the key performance indicators, the controller of the ego vehicle **100** may determine whether the maneuver of the ego vehicle **100** triggers congestion or string instability in the target lane **104**.

[0050] In step **330**, the controller of the ego vehicle identifies a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane. For example, by referring to FIG. **1**B, the ego vehicle **100** simulates its changing lanes from the lane **102** to the target lane **104** and the simulation results in string instability in the target lane **104**, e.g., traffic congestion or stop-and-go traffic jam. Then, the ego vehicle **100** identifies the connected vehicle **110** in the target lane **104** as illustrated in FIG. **4**A.

[0051] In step **340**, the controller of the ego vehicle requests that the identified connected vehicle change lanes from the target lane to another lane to obtain an empty space between a vehicle in front of the identified connected vehicle and a vehicle behind the identified connected vehicle. For example, by referring to FIG. **4**A, the controller of the ego vehicle **100** transmits a maneuver message **410** to the connected vehicle **110** to change lanes from the target lane to another lane **106**. In response to receiving the maneuver message **410**, the connected vehicle **110** changes lanes from the target lane **104** to the lane **106** such that an empty space between a vehicle **124** in front of the identified connected vehicle **110** and a vehicle **125** behind the identified connected vehicle **110**. Then, the ego vehicle **100** changes lanes from the lane **102** to the target lane **104** as illustrated in FIG. **4**B. In some embodiments, the ego vehicle **100** changes lanes from the lane **102** to the target lane **104** at the same time or before the connected vehicle **110** changes lanes from the target lane **104** to another lane **106**.

[0052] In response to the ego vehicle **100** moving into the target lane **104**, a group of vehicles **122**, **123**, **124** may show unstable behavior **420** because the vehicles **122**, **123**, **124** show cascading of braking as illustrated in FIG. **4**C. However, because an additional space is now generated between the vehicle **124** and the vehicle **125**, the vehicles **125** and **126** may not need to brake significantly, and show stable behavior or string stability **430**, as illustrated in FIG. **4**C.

[0053] FIG. **5** depicts an overall flowchart of performing density reduction, according to one or more embodiments shown and described herein. The ego vehicle and vehicle n in FIG. **5** may correspond to the ego vehicle **100** and the connected vehicle **110** in FIGS. **4**A-**4**C, respectively.

[0054] In step **502**, the ego vehicle **100** determines that the traffic in the target lane **104** may be string unstable if the ego vehicle **100** changes lanes from the lane **102** to the target lane **104**. In step **511**, the ego vehicle **100** initiates finding a potential cooperating vehicle. In step **512**, the ego vehicle **100** starts from a first candidate, e.g., the connected vehicle **110**. Then, the ego vehicle **100** transmits a request for cooperation to the connected vehicle **110** in step **513**. The connected vehicle **110** receives the request and identifies potential new target lanes in step **521**. For example, by referring to FIG. **6**A, the connected vehicle **110** may identify two potential new target lanes, lanes **102** and **106**. In step **522**, the connected vehicle **110** selects the lane **102**. In step **523**, the connected vehicle **523** evaluates safety, efficiency, and comfort of the lane **102**.

[0055] In step **524**, the connected vehicle determines whether changing lanes from the current lane

104 to the lane **102** is feasible. In this case, the connected vehicle **110** may determine that changing lanes from the current lane **104** to the lane **102** is not feasible because there is an obstacle in the lane **102**. Then, the connected vehicle **110** determines whether there is another potential target lane. If there is no other potential target lane, the connected vehicle **110** declines the request in step **527**, and transmits the decline to the ego vehicle **100**. If there is another potential target lane, the connected vehicle **110** selects another target lane, for example, the lane **106**, in step **528**. Then, the connected vehicle **110** evaluates safety, efficiency, and comfort of the lane **106** in step **523**, and determines that changing lanes from the current lane **104** to the lane **106** is feasible in step **524**. Then, the connected vehicle **110** accepts the request from the ego vehicle **100**, and transmits the acceptance to the ego vehicle **100** in step **525**.

[0056] The ego vehicle **100** determines whether the request is approved or not in step **514**. If the request is not approved by the connected vehicle **110**, the ego vehicle **100** determines whether there is next cooperating vehicle in step **516**. If there is no next cooperating vehicle, the ego vehicle **100** determines that changing lanes without causing string instability is infeasible in step **517**. If there is a next cooperating vehicle, the ego vehicle selects a next vehicle in step **518**, and transmits a request to the next vehicle in step **513**. The next vehicle performs the similar process as the connected vehicle **110**.

[0057] If the request is approved by the connected vehicle **110**, the ego vehicle **100** initiates preforming mitigation and transmits a mitigation instruction to the connected vehicle **110**. In response to receiving the mitigation instruction, the connected vehicle **110** changes lanes from the target lane **104** to the lane **106** in step **529**. In parallel with the changing lanes by the connected vehicle **110**, the ego vehicle **100** changes lane from the lane **102** to the target lane **104** in step **519**.

[0058] FIG. **6** depicts a flowchart for performing longitudinal control in a target lane including both human-driven and connected cooperating vehicles, according to one or more embodiments shown and described herein. The flowchart is described with reference to FIGS. **2** and **7A-7D** of the present application.

[0059] In step **610**, a controller of the ego vehicle obtains traffic data from a target lane. For example, by referring to FIG. **7**A, the ego vehicle **100** may obtain traffic data from the target lane **104**. The traffic information may include the presence and speed of connected or unconnected vehicles in the target lane **104**, the traffic density of vehicles in the target lane **104**, and the like. In this example, the ego vehicle **100** obtains information about the present and speed of the unconnected vehicles **121**, **122**, **123**, **124**, **125**, **126** and the connected vehicle **110**. The presence, speeds and/or accelerations of connected or unconnected vehicles in the target lane **104** may be obtained by the sensors of the ego vehicle **100**. The traffic density may be estimated by a world model. The world model receives sensor data, wireless messages, and GPS data as input, and outputs traffic density estimation for the target lane **104**. The ego vehicle **100** may also learn a car-following model of vehicles in the target lane **104**.

[0060] Referring back to FIG. **6**, in step **620**, the controller of the ego vehicle determines whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data. For example, the controller of the ego vehicle **100** may simulate the ego vehicle changing lanes from the lane **102** to the target lane **104** in FIG. **7**A using the traffic data and the learned car following model obtained in step **610**. The controller of the ego vehicle **100** may predict oscillations **710** of the unconnected vehicles **122**, **123**, **124** caused by the lane changing maneuver of the ego vehicle **100** as illustrated in FIG. **7**A, and determines whether the traffic in the target lane **104** becomes string unstable based on the predicted oscillations. In some embodiments, the ego vehicle **100** may determine key performance indicators, e.g., traffic flow, oscillations in acceleration profiles, driver comfort, and timeliness of the maneuver, caused by the lane changing maneuver of the ego vehicle **100** by running simulations of the ego vehicle **100** and vehicles in the target lane **104**. The simulation may use IDM (intelligent driving model) for upstream vehicles. Based on the key performance indicators, the

controller of the ego vehicle **100** may determine whether the maneuver of the ego vehicle **100** triggers congestion or string instability in the target lane **104**.

[0061] Referring back to FIG. **6**, in step **630**, the controller of the ego vehicle identifies a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane. For example, by referring to FIG. **7**A, the ego vehicle **100** simulates its changing lanes from the lane **102** to the target lane **104** and the simulation results in string instability in the target lane **104**, e.g., traffic congestion or stop-and-go traffic jam. Then, the ego vehicle **100** identifies the connected vehicle **110** in the target lane **104**.

[0062] Referring back to FIG. **6**, in step **640**, the controller of the ego vehicle generates a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car following models. In embodiments, the ego vehicle **100** generates a suggested profile for the connected vehicle **110** based on the traffic data collected in step **610** and the learned car following models, that mitigates disturbance or string instability in the target lane **104**. For example, by referring to FIG. **7**A, the ego vehicle **100** predicts speed or acceleration profile oscillations of the vehicles **122**, **123**, **124** in the target lane **104** based on car-following behaviors and collected traffic data such as the positions of the vehicles **122**, **123**, **124** in the target lane **104**. Then, the ego vehicle **100** generates a speed profile for the connected vehicle **110** based on the predicted speed or acceleration profile oscillations of the vehicles **122**, **123**, **124**. The speed profile for the connected vehicle **110**, if followed by the connected vehicle **110**, creates a gap between the connected vehicle and the unconnected vehicle **124** and mitigates speed or acceleration oscillations of the connected vehicle **110** and the vehicles behind the connected vehicle **110**.

[0063] Referring back to FIG. **6**, in step **650**, the controller of the ego vehicle requests that the identified connected vehicle drive based on the suggested speed profile. In embodiments, by referring to FIG. **7**B, the ego vehicle **100** transmits a maneuver message **720** to the connected vehicle **110**. The maneuver message **720** includes the suggested speed profile for the connected vehicle **110**. In response to receiving the maneuver message **720**, the connected vehicle **110** brakes smoothly based on the suggested speed profile such that the space **732** between the vehicle **124** and the connected vehicle **110** becomes greater, as illustrated in FIG. **7**C. Then, the ego vehicle **100** changes lanes from the lane **102** to the target lane **104** as illustrated in FIG. **7**C. Specifically, the ego vehicle **100** moves into the space **734** between the vehicle **121** and the vehicle **122**. In some embodiments, the ego vehicle **100** changes lanes from the lane **102** to the target lane **104** at the same time or before the connected vehicle **110** changes its speed.

[0064] In response to the ego vehicle **100** moving into the target lane **104**, a group of vehicles **122**, **123**, **124** may show unstable behavior **740** because the vehicles **122**, **123**, **124** show cascading of braking. However, because an additional space is now generated between the vehicle **124** and the connected vehicle **110**, the connected vehicle **110** and the unconnected vehicles **125** and **126** may not need to brake significantly, and show stable behavior or string stability **750**, as illustrated in FIG. **7**D.

[0065] FIG. **8** depicts an overall flowchart of performing longitudinal control including both human-driven and connected cooperating vehicles, according to one or more embodiments shown and described herein. The ego vehicle and vehicle n in FIG. **8** may correspond to the ego vehicle **100** and the connected vehicle **110** in FIGS. **7**A-**7**D, respectively.

[0066] In step **802**, the ego vehicle **100** determines that the traffic in the target lane **104** may be string unstable if the ego vehicle **100** changes lanes from the lane **102** to the target lane **104**. In step **811**, the ego vehicle **100** initiates finding a potential cooperating vehicle. In step **812**, the ego vehicle **100** starts from a first candidate, e.g., the connected vehicle **110**. The ego vehicle **100** estimates potential oscillations for the connected vehicle **110** based on the vehicles locations and learned car following behavior obtained in step **816**. Based on the estimated potential oscillations, the ego vehicle generates a suggested speed profile for the connected vehicle **110** in step **814**. Then, the ego vehicle **100** transmits a request for cooperation to the connected vehicle in step **815**. The

connected vehicle **110** receives the request and evaluates safety, efficiency, and comfort of the suggested speed profile received from the ego vehicle **100** in step **830**. In step **831**, the connected vehicle **110** determines whether following the suggested speed profile is feasible. For example, the connected vehicle **110** may determine whether following the suggested speed profile is feasible based on current traffic data in the target lane **104** including the presence of other vehicles and car following models of the other vehicles in the target lane **104**.

[0067] If it is determined that following the suggested speed profile is feasible, the connected vehicle **110** accepts the request from the ego vehicle **100** and transmits an approval message to the ego vehicle **100** in step **832**. If it is determined that following the suggested speed profile is not feasible, the connected vehicle **110** declines the request from the ego vehicle **100** and transmits a decline message to the ego vehicle **100** in step **833**.

[0068] The ego vehicle **100** determines whether the request is approved or not in step **817**. If the request is not approved by the connected vehicle **110**, the ego vehicle **100** determines whether there is next cooperating vehicle in step **819**. If there is no next cooperating vehicle, the ego vehicle **100** determines that changing lanes without causing string instability is infeasible in step **821**. If there is a next cooperating vehicle, the ego vehicle selects the next cooperating vehicle in step **820**, and repeats the steps **813**, **814**, **815**. The next cooperating vehicle performs the similar process as the connected vehicle **110**.

[0069] If the request is approved by the connected vehicle **110**, the ego vehicle **100** initiates preforming mitigation and transmits a mitigation instruction to the connected vehicle **110** in step **818**. In response to receiving the mitigation instruction, the connected vehicle **110** follows the suggested speed profile in step **834**. The ego vehicle **100** changes lane from the lane **102** to the target lane **104** in step **823**.

[0070] FIGS. **9**A-**9**D depict an example of performing longitudinal control in a fully connected scenario, according to one or more embodiments shown and described herein.

[0071] In FIG. **9**A, traffic in the target lane **104** includes both connected vehicles **911**, **912**, **913**, **914**, **915**, **916** (C**1**, . . . , C**6**) as well as connected cooperating vehicles **110** (A**1**). The ego vehicle **100** decides to change lanes from the lane **102** to the target lane **104**. In this scenario, connected vehicles **912**, **913**, **914** are connected vehicles. However, the connected vehicles **912**, **913**, **914** cannot deploy actions to mitigate the potential disturbances in contrast with the connected cooperating vehicle **110**. The connected vehicles **912**, **913**, **914** can send information regarding their real-time oscillations to the connected cooperating vehicle **110**. The ego vehicle **100** predicts whether its lane change action will disturb traffic in the target lane **104**.

[0072] In this scenario, in addition to the traffic information and the learned behavior models, the present system utilizes oscillation information from connected vehicles to better control the acceleration of connected vehicles **912**, **913**, **914** in the target lane to mitigate the disturbances. The present system collects oscillations data from connected vehicles and uses them to update the speed profile and improve the controller.

[0073] By referring to FIG. **9**B, the ego vehicle **100** requests cooperation from the connected cooperating vehicle **110** and sends a maneuver message **920** including a suggested speed profile to the connected cooperating vehicle **110**. Once the connected cooperating vehicle **110** accepts the request from the ego vehicle **100**, the ego vehicle **100** sends maneuver messages **920** including requests for sharing oscillation data with the connected cooperative vehicle **110** to the connected vehicles **912**, **913**, **914**.

[0074] By referring to FIG. **9**C, the connected vehicle **912** monitors the oscillation in its acceleration profile. Once oscillation detected, the connected vehicle **912** sends state data **930** such as oscillation amplitude, wavelength, and period to the connected cooperating vehicle **110**. The connected cooperating vehicle **110** uses the data to update its speed profile and achieve optimum performance.

[0075] Similarly, the connected vehicles **913** and **914** may also share their state data **944** and **942**

such as oscillation amplitude, wavelength, and period with the connected cooperating vehicle **110** as illustrated in FIG. **9**D. The connected cooperating vehicle **110** updates its speed profile in real-time. The gap created by the connected cooperating vehicle **110** mitigates oscillations and leads to smooth behavior in the target lane **104**.

[0076] FIGS. **10**A-**10**D depict an example of performing longitudinal control in a partially connected scenario, according to one or more embodiments shown and described herein.

[0077] In this scenario, some of the vehicles in the target lane **104** are not connected vehicles. For example, by referring to FIG. **10**A, vehicles **121**, **122**, **123**, **124**, **125** are not connected vehicles, the vehicle **911** is a connected vehicle, and the vehicle **110** is a connected cooperating vehicle **110**.

[0078] By referring to FIG. **10**B, the ego vehicle **100** requests cooperation from the connected cooperating vehicle **110** and sends a maneuver message **1020** including a suggested speed profile to the connected cooperating vehicle **110**. Once the connected cooperating vehicle **110** accepts the request from the ego vehicle **100**, the ego vehicle **100** sends a maneuver message **1020** including a request for sharing oscillation data with the connected cooperative vehicle **110** to the connected vehicle **911**.

[0079] By referring to FIG. **10**C, the connected vehicle **110** changes lanes from the lane **102** to the target lane **104**. By referring to FIG. **10**D, the connected vehicle **911** monitors the oscillation in its acceleration profile. Once oscillation detected, the connected vehicle **911** sends state data **1040** such as oscillation amplitude, wavelength, and period to the connected cooperating vehicle **110**. The connected cooperating vehicle **110** uses the data to update its speed profile and achieve optimum performance.

[0080] By referring to FIG. **10**E, the vehicles **122** and **123** and the connected vehicle **911** show unstable behavior **1050** due to the lane changing maneuver of the ego vehicle **100**. However, the connected vehicle **110** and the vehicles **124** and **125** show stable behavior **1060** because the gap created by the connected cooperating vehicle **110** mitigates oscillations and leads to smooth behavior in the target lane **104**.

[0081] FIGS. **11**A and **11**B depict an overall flowchart of performing longitudinal control in a fully or partially connected scenario, according to one or more embodiments shown and described herein. The ego vehicle and vehicle n in FIGS. **11**A and **11**B may correspond to the ego vehicle **100** and the connected vehicle **110** in FIGS. **9**A-**10**E, respectively, and the connected vehicle c in FIGS. **11**A and **11**B may correspond to one of the connected vehicles **912**, **913**, **914** in FIGS. **9**A-**9**D or the connected vehicle **911** in FIGS. **10**A-**10**E

[0082] In step **1102**, the ego vehicle **100** determines that the traffic in the target lane **104** may be string unstable if the ego vehicle **100** changes lanes from the lane **102** to the target lane **104**. In step **1111**, the ego vehicle **100** initiates finding a potential cooperating vehicle. In step **1112**, the ego vehicle **100** starts from a first candidate, e.g., the connected vehicle **110**. In step **1113**, the ego vehicle **100** identifies connected vehicles in the target lane **104** between the ego vehicle **100** and the connected vehicle **110**. For example, the ego vehicle **100** may identify connected vehicles **912**, **913**, **914** in FIG. **9**A. In step **1114**, the ego vehicle **100** estimates potential oscillations for the connected vehicle **110** based on the vehicles locations and learned car following behavior obtained in step **1126**. Based on the estimated potential oscillations, the ego vehicle generates a suggested speed profile for the connected vehicle **110** in step **1115**. Then, the ego vehicle **100** transmits a request for cooperation to the connected vehicle in step **1116**.

[0083] The connected vehicle **110** receives the request and evaluates safety, efficiency, and comfort of the suggested speed profile received from the ego vehicle **100** in step **1130**. In step **1131**, the connected vehicle **110** determines whether following the suggested speed profile is feasible. For example, the connected vehicle **110** may determine whether following the suggested speed profile is feasible based on current traffic data in the target lane **104** including the presence of other vehicles and car following models of the other vehicles in the target lane **104**.

[0084] If it is determined that following the suggested speed profile is feasible, the connected

vehicle **110** accepts the request from the ego vehicle **100** and transmits an approval message to the ego vehicle **100** in step **1132**. If it is determined that following the suggested speed profile is not feasible, the connected vehicle **110** declines the request from the ego vehicle **100** and transmits a decline message to the ego vehicle **100** in step **1133**.

[0085] The ego vehicle **100** determines whether the request is approved or not in step **1117**. If the request is not approved by the connected vehicle **110**, the ego vehicle **100** determines whether there is a next cooperating vehicle in step **1120**. If there is no next cooperating vehicle, the ego vehicle **100** determines that changing lanes without causing string instability is infeasible in step **1121**. If there is a next cooperating vehicle, the ego vehicle selects a next vehicle in step **1122**, and repeats the steps **1114**, **1115**, **1116**. The next vehicle performs the similar process as the connected vehicle **110**.

[0086] If the request is approved by the connected vehicle **110**, the ego vehicle **100** requests connected vehicles, e.g., the connected vehicles **912**, **913**, **914** in **9**B or the connected vehicle **911** in FIG. **10**B to share their states such as oscillation amplitude, wavelength, and period with the connected vehicle **110**. In response to receiving the requests from the ego vehicle **100**, the connected vehicles **912**, **913**, **914** monitor their oscillations in step **1140**, and determine whether the accelerations or speeds are oscillating in step **1141**. If the accelerations or speeds are not oscillating, the connected vehicles **912**, **913**, **914** sends no oscillation state to the connected vehicle **110** in step **1143**. If the accelerations or speeds are oscillating, the connected vehicles **912**, **913**, **914** sends oscillation state to the connected vehicle **110** in step **1142**.

[0087] After or at the same time of transmitting a request to share state data to connected vehicles, e.g., the connected vehicles **912**, **913**, **914** in **9**B or the connected vehicle **911** in FIG. **10**B, the ego vehicle **100** initiates preforming mitigation and transmits a mitigation instruction to the connected vehicle **110** in step **1119**. In response to receiving the mitigation instruction, the connected vehicle **110** starts mitigation with the initial suggested speed profile in step **1134** and follows the suggested speed profile in step **1135**. In step **1136**, the connected vehicle **110** receives oscillation state data from other connected vehicles such as the connected vehicles **912**, **913**, **914** in **9**B or the connected vehicle **911** in FIG. **10**B. Then, the connected vehicle **110** determines whether the traffic is smooth or not in step **1137**. If the traffic is smooth, the connected vehicle **110** may not need to take further actions. If the traffic is not smooth, the connected vehicle **110** determines whether there is any new oscillation state in step **1138**. If there is no new oscillation state, the connected vehicle **110** repeats the steps **1135**, **1136**, **1137**. If there is a new oscillation state, the connected vehicle **110** updates the speed profile of the connected vehicle **110** based on the new oscillation state in step **1139**, and repeats the steps **1135**, **1136**, **1137**.

[0088] It should be understood that embodiments described herein are directed to a method for mitigating traffic congestion caused by a lane changing maneuver. In embodiments, the present disclosure utilize a density reduction approach where the system uses traffic information obtained by connected vehicles as well as the learned behavioral models to estimate potential disturbances and instructs connected cooperating vehicles to change lanes from a target lane to another lane. In some embodiments, the present disclosure utilizes longitudinal control of cooperating connected vehicles in the target lane to mitigate the disturbances. For the longitudinal control, the system considers a no real-time observation scenario where the system utilizes traffic information and learned behaviors to generate speed profile for the cooperating vehicle in the target lane. The system may also consider a full or partial real-time observation scenario where the systems utilizes real-time data obtained from connected vehicles to monitor characteristics of oscillations (e.g., amplitudes, wavelength, period) to better plan speed profiles of the cooperating vehicle. The present system improves performance of connected vehicles as well as the whole traffic system in terms of performance measures such as efficiency, comfort, and reliability.

[0089] It is noted that the terms "substantially" and "about" may be utilized herein to represent the inherent degree of uncertainty that may be attributed to any quantitative comparison, value,

measurement, or other representation. These terms are also utilized herein to represent the degree by which a quantitative representation may vary from a stated reference without resulting in a change in the basic function of the subject matter at issue.

[0090] While particular embodiments have been illustrated and described herein, it should be understood that various other changes and modifications may be made without departing from the spirit and scope of the claimed subject matter. Moreover, although various aspects of the claimed subject matter have been described herein, such aspects need not be utilized in combination. It is therefore intended that the appended claims cover all such changes and modifications that are within the scope of the claimed subject matter.

Claims

1. A method for controlling longitudinal movements of vehicles, the method comprising: obtaining traffic data from a target lane; determining whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data; identifying a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane; generating a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car-following models; and requesting that the identified connected vehicle drive based on the suggested speed profile.

2. The method of claim 1, wherein the identified connected vehicle follows the suggested speed profile to create a first empty space between the identified connected vehicle and a vehicle in front of the identified connected vehicle in the target lane.

3. The method of claim 2, further comprising: instructing the ego vehicle to enter into a second empty space in the target lane by changing lanes from a current lane to the target lane.

4. The method of claim 3, wherein the first empty space is further away from the ego vehicle than the second empty space.

5. The method of claim 1, further comprising: instructing other connected vehicles in the target lane to transmit state data to the identified connected vehicle.

6. The method of claim 5, wherein the state data includes speed or acceleration oscillations of the other connected vehicles in the target lane.

7. The method of claim 1, further comprising: receiving a decline from the identified connected vehicle in the target lane; identifying another connected vehicle in the target lane; generating a suggested speed profile for the identified another connected vehicle based on the traffic data and the learned car-following models; and requesting that the identified another connected vehicle drive based on the suggested speed profile for the identified another connected vehicle.

8. A system for mitigating traffic congestion, the system comprising: a processor programmed to perform operations comprising: obtaining traffic data from a target lane; determining whether a traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane based on learned car-following models and the traffic data; identifying a connected vehicle in the target lane in response to determining that the traffic in the target lane becomes string unstable in response to an ego vehicle moving to the target lane; generating a suggested speed profile for the identified connected vehicle based on the traffic data and the learned car-following models; and requesting that the identified connected vehicle drive based on the suggested speed profile.

9. The system of claim 8, wherein the identified connected vehicle follows the suggested speed profile to create a first empty space between the identified connected vehicle and a vehicle in front of the identified connected vehicle in the target lane.

10. The system of claim 9, wherein the processor is further programmed to perform operations comprising: instructing the ego vehicle to enter into a second empty space in the target lane by changing lanes from a current lane to the target lane.

11. The system of claim 10, wherein the first empty space is further away from the ego vehicle than the second empty space.

12. The system of claim 8, wherein the processor is further programmed to perform operations comprising: instructing other connected vehicles in the target lane to transmit state data to the identified connected vehicle.

13. The system of claim 12, wherein the state data includes speed or acceleration oscillations of the other connected vehicles in the target lane.

14. The system of claim 8, wherein the processor is further programmed to perform operations comprising: receiving a decline from the identified connected vehicle in the target lane; identifying another connected vehicle in the target lane; generating a suggested speed profile for the identified another connected vehicle based on the traffic data and the learned car-following models; and requesting that the identified another connected vehicle drive based on the suggested speed profile for the identified another connected vehicle.
